Assessment of Anterior Loop of Inferior Alveolar Nerve – A Cone Beam Computed Tomography Study

Abstract

Introduction: The anterior loop (AL) of the inferior alveolar nerve (IAN) and the mental foramen (MF) are important anatomical structures that should be taken into consideration during preoperative planning in the anterior mandibular region. This study aims to assess the prevalence, length, and type of the AL of the IAN in males and females in a South Indian population. Additionally, the distance from the MF to the lower border of the mandible is assessed. **Materials and Methods:** A total of 115 cone-beam computed tomography (CBCT) scans of 230 sides of mandibles were taken using a Carestream Select CS9300 CBCT machine (Carestream Dental LLC, Atlanta, USA). The scans were selected from archives and divided into three different age groups (<40, 41–60, >61 years). The scans were analyzed to detect the canal of the AL of the inferior alveolar nerve canal (IANC). The IANC, along with the AL canal and part of the incisive nerve canal, was traced using the CS 9300 software. The length of the mandibular nerve was measured for each patient in cross-sectional and panoramic views. **Results:** The AL was present in 92.6% of the 115 participants. Overall anterior loop length ranged between 0.9 and 15.2 mm. The mean length of AL in panoramic view on the right side was 3.284 ± 2.314 mm and it was 3.015 ± 2.151 mm on the left side. Y-shaped AL was more predominant when compared to T-shaped AL in the sample. **Conclusion:** The prevalence of AL was relatively higher in subjects ranging from 41 to 60 years with a slight increase in female predominance.

Keywords: Anterior loop, cone-beam computed tomography, mental foramen, inferior border of the mandible

Introduction

The mandibular nerve is the third division of the trigeminal nerve. After passing through the mandibular foramen, it is called the inferior alveolar nerve (IAN). The section of the nerve anterior to the mental foramen (MF) and just before its ramification to the incisive nerve is called the anterior loop (AL) of IAN. Surgeries in that region may result in neurosensory disturbances such as paresthesia of the lip and chin.^[1]

The AL of IAN cannot be detected clinically, but the inferior alveolar nerve canal (IANC) can be seen in diagnostic imaging, which includes dental panoramic radiography, multi detector panoramic computed tomography (MDCT scans), and cone-beam computed tomography (CBCT). CBCT superiorly visualizes the anatomical variations of IANC, which infers the path of the IAN. Visualization of the path of the nerve can

prevent nerve damage and resultant complications during surgery.^[1] While similar studies have been carried out on other populations, this study aims to determine whether the differences found in a South Indian population are significant enough to warrant separate surgical recommendations.

Materials and Methods

The present study was carried out using CBCT images of patients taken for various clinical indications during the period from December 2018 to May 2020. All images were obtained using a single Carestream select 9300 CBCT machine (Carestream Dental LLC, Atlanta, USA). Analysis of the AL of the IANC was carried out for both sides of each scan by tracing the inferior alveolar canal and its anterior

branches. Ethical approval for this study (Pr.149/IEC/SIBAR/2018) was provided by the ethical committee of Sibar Institute of Dental Sciences, Guntur, on 29/10/2018.

In this study, the assessment of AL and its measurements were done in all three projections (axial, coronal cross-sectional, and panoramic views) using the CBCT scans viewed with the Carestream software. The IANC was traced with the software along with the AL and part of the incisive nerve canal. The entry and exit of the MF were then located from the cross-sectional view. Vertical lines were drawn on the panoramic view from the slice that corresponded to the anterior and posterior walls of the MF and the most anterior point of the anterior nerve loop length (ANLL) as seen from the cross-sectional view. The vertical length of the nerve was estimated from the canal to the opening of the MF from the cross-sectional view and translated to the panoramic view and marked as point 1. Point 2 was marked on the most anterior confinement of the AL, and a measurement was made from point 1 to point 2 [Figure 1]. This provided an actual length for the ANLL compared with the anteroposterior spread of the loop as it followed the diagonal trajectory of the nerve in panoramic view.

The visualization of sections in the three spatial dimensions (axial, sagittal, and coronal sections) is known as multiplanar

reconstruction. The type of AL in the sagittal view and length of the AL in the axial view was measured by marking three lines. The posterior part of the MF was drawn as the third line, the anterior part of the MF was drawn as the second line, and the anterior most confinement of the AL was drawn as the first line. Measurement was made from the first line to the second line. This provided an actual length for the AL [Figure 2] in axial view.

Cross sections of 1 mm thickness were obtained in cross-sectional slices. The length of the loop has been measured by counting the number of consecutive contiguous vertical cross sections performed between the anterior border of the MF and the anterior border of the loop. This number is multiplied by the resolution of the slice [Figure 3].

We used the classification described by Solar *et al.*^[2] for evaluating the various types of AL of IAN [Figure 4].

Figure 5: CBCT images of distance from mental foramen to the lower border of the mandible. CBCT, cone-beam computed tomography

- Type 1 – the AL is absent.
- Type 2 – the AL is T shaped.
- Type 3 – the AL is Y shaped.

The distance from the lower point of the MF to the lower border of the mandible was drawn and measured [Figure 5].

Results

The total number of subjects included in the study group was 115 and the total number of sides observed was 230. The AL was present in 92.6% of the 230-subject sample [Table 1]. The subjects in the study group comprised 33.9% (39) males and 66.1% (76) females, suggesting a female predominance in this sample. The length of the AL was found to be greater in the females on the left side, whereas it was found to be greater in males on the right side in all the three age groups. The AL prevalence and its length were greater in the 41 to 60 years age group than in other age groups. Overall anterior loop length (ALL) ranged from 0.9 to 15.2 mm, with a mean length

Table 1: Prevalence of anterior loop

	Present		No data/ Absent	
	N	%	N	%
Anterior loop right side	110	95.7%	5	4.3%
Anterior loop left side	103	89.6%	12	10.4%

Table 2: Length of the anterior loop in panoramic, oblique, and cross-sectional slicing views

Length of anterior loop	N	Mean	Standard deviation	t value	Significant
Panoramic side	Right	115 3.284	2.3149	15.215	0.0001*
	Left	115 3.015	2.1512	15.029	0.0001*
Oblique side	Right	115 3.211	1.8317	18.801	0.0001*
	Left	115 3.313	2.2083	16.088	0.0001*
Cross-sectional slicing side	Right	115 2.61	1.197	23.367	0.0001*
	Left	115 2.43	1.352	19.318	0.0001*

One sample, t test, *statistically significant

of AL in panoramic view on the right side and left side being 3.284 ± 2.314 and 3.015 ± 2.151 mm, respectively [Table 2]. Measurements were also done in oblique and cross-sectional views, in which the oblique view demonstrated similar measurements to the panoramic view, whereas in cross-sectional view, it showed a variation in the length of AL. The Y shape type of AL was more predominant when compared to the T shape in the sample [Chart 1]. Analyzing the relationship between the length of the AL and distance from the MF to the lower of the mandible on the right side depicts that with a one unit increase in distance from the right MF to the lower border of the mandible, the length of AL increased by 0.136 times and on the left side, with a one unit increase in distance from right MF to the lower

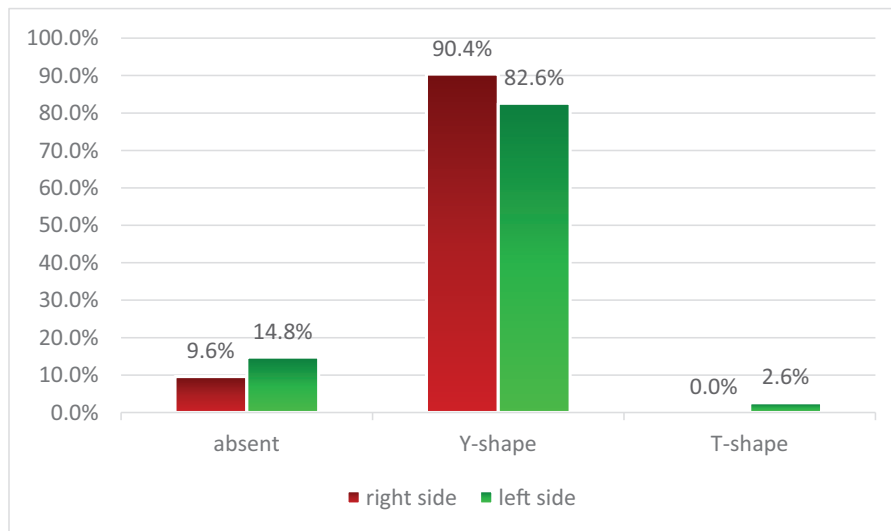

Chart 1: Type of anterior loop

border of the mandible, the length of AL increased by 0.163 times. This finding is statistically significant with a $P < 0.05$.

Discussion

The AL can be described as the extension of the mandibular canal anterior to the MF. It is formed just before the ramification of the mandibular canal into the incisive canal.^[3] It includes the mental and incisive nerves simultaneously; therefore, caution should be taken during surgical procedures in the interforaminal region to avoid nerve damage.^[3] Surgery in the area of the anterior mandible may violate the AL, resulting in neurosensory disturbances in the area of the lower lip and chin.^[1]

Many researchers have made attempts to detect the prevalence and location of the AL, as well as the anterior loop length (ALL).^[4] To avoid injury to the IAN, a 5 mm “safe” distance to the most distal fixture from the AL and a 5 mm distance from the MF for harvesting chin bone for grafts have been proposed.^[1]

CBCT is a highly efficient imaging modality for the assessment of vital anatomical structures. Moreover, CBCT provides acceptable three-dimensional (3D) views and accessibility to the craniofacial structures in comparison with the conventional radiographic techniques. Because of this, CBCT is preferred to MDCT and most often used in dental practice due to its advantages, including a lower cost and a lower radiation dose, in combination with the fact that CBCT image quality is comparable or even superior to that of MDCT for evaluating dento-maxillofacial structures.^[5]

In the present study, 230 CBCT scans of the right and left sides were evaluated, in which the AL of the IAN canal was identified in 213 scans (92.6%). Similar studies done in the literature using 3D CBCT scans had proven to exhibit high precision and reliability in the diagnosis of the AL and other

bony anatomical landmarks of the mandible with great reliability to identify the presence and measurement of length. In a study done by Wong and Patil,^[3] it was noted that the AL was present in 94% of the 100 CBCT scans in three different ethnic groups (33 Malaya, 33 India, 34 Chinese). Lu *et al.*^[6] had done a study on 366 CBCT images in the USA population in which the prevalence of AL was seen in 85.2% of scans. Parnia *et al.*^[7] had done a study on 96 CBCT scans in the Irani population, of which the AL was visualized in 84% of the CBCT scans.

In the present study, 115 CBCT scans were evaluated, out of which 33.9% were of males and 66.1% were of females. On comparing the prevalence of AL in both genders, AL was found to be more in females than in males, but this was not statistically significant. In a previous study done by Lu *et al.*^[6] on 68 CT scans of the mandible for the presence of AL on each side, 113 sides, that is, 68 patients out of 136 mandible sides, exhibited no difference in the prevalence of AL between males and females. Here some scans are single sided Siddiqui *et al.*^[1] conducted a similar study on 193 CBCT scans. The prevalence of AL was 40.4% among males and 33.7% among females. Nakib *et al.*^[8] had done a study on 400 CBCT images in which AL was noted in 56% males and 44% females, but this variable was statistically significant.

In the present study, the prevalence of AL was categorized based on age into three groups: less than 40 years, 41 to 60 years, and greater than 60 years. The prevalence of AL was found to be slightly greater in the age group of 41 to 60 years. Kajan and Salari^[9] had done a study on 84 mandibular CBCT scans, and they found a significant difference in determining the visibility of AL in different age groups. Their results showed that the prevalence of the AL: was lower in patients over 40 years of age. do Nascimento *et al.*^[5] conducted a study on CBCT scans of 250 patients among different age groups, and they reported the highest prevalence of AL in subjects in the second to fifth decades of life. Apostolakis and

Brown^[10] had done a study on 93 CBCT images in the Greek population in which the prevalence of AL was 48%. No significant correlation with the age ranges of individuals was found.

In the present study, the mean length of AL in the panoramic view was 3.284 ± 2.314 mm on the right side and 3.015 ± 2.151 mm on the left side ($P = 0.001$), whereas in the oblique view, it was 3.211 ± 1.8317 mm on the right side and 3.313 ± 2.2083 mm on the left side ($P = 0.001$). In cross-sectional slicing, it was 2.61 ± 1.19 mm on the right side and 2.43 ± 1.35 mm on the left side ($P = 0.001$). The greatest length of AL was 15.1 mm and the lowest length was about 0.9 mm. Panoramic and oblique view measurements of the length of AL did not demonstrate any statistical variation, but in cross-sectional slicing, there was a marked difference. This finding might be attributed to the thickness of the slicing in this view. Rosa *et al.*^[11] conducted a study on 352 CBCT scans of the mandible and reported that in 21 of the images, the length of the AL exceeded 4.5 mm, with the greatest length being 7 mm. Apostolakis and Brown^[10] had done a study on 93 CBCT scans with a prevalence of AL in 62% of patients, and they found the mean and range of ALL as 0.89 and 0.0 to 5.7 mm, respectively. The longest loop measured was 5.7 mm. In a study done by Kaya *et al.*^[12] on 73 panoramic radiographs and spiral CT, they reported that the mean length of AL was 0.71 ± 0.21 mm greater in panoramic radiographs than in MDCT.

Parnia *et al.*^[7] conducted a study on 96 CBCT scans in the Irani population and noticed the mean length of AL to be 3.54 mm in the study group. do Nascimento *et al.*^[5] performed a study on 250 CBCT scans and noticed that the mean length of the AL was 1.1 mm, and the largest ALL was 4 mm. The AL length had shown a mean of 0.2 to 7.61 mm presentation in various studies, but most of these studies had shown a mean length concentrating around 2 to 3 mm. Therefore, the proposed 5 mm safe distance appears to be ideal for surgical intervention in that region.

In the present study, comparing the length of AL in both genders, the mean length of AL was greater on the right side in males and on the left side in females, with a statistically significant variation. According to the study conducted by Rosa *et al.*,^[13] the AL was significantly longer in men than in women. do Nascimento *et al.*^[5] performed a study on 250 CBCT scans, and their results showed the mean length of the AL was 1.1 mm, and AL was more prevalent in male patients compared to the females.

In the present study, the mean length of the AL was found to be greater in the 41 to 60 age group. do Nascimento *et al.*^[5] had done a study on 250 CBCT scans where they found that AL was more prevalent in young patients compared to the older individuals.

In the present study, Y-shaped AL was noticed in 90.4% of cases on the right side and 82.6% of cases on the left side. On

comparing the type of AL, Y shape was more predominant when compared to the T shape in the sample, with no significant difference between the right and left sides of the mandible. Shaban *et al.*^[4] conducted a study on 71 CBCT images, of which 36 were males and 35 were females, and they found that type-III AL was a more prevalent variant and type-I (Y type) was the least prevalent type. Demir *et al.*^[14] performed a study on 279 CBCT scans in the Turkish population. It was found that type-III AL (not appreciated) was a more prevalent variant and type-I AL (Y shape) was the least prevalent type.

In the present study, the mean distance from the MF to the lower border of the mandible was greater on the right side (8.454 mm) than on the left side (7.939) and greater in males than in females. It was also greater in the age groups between 41 and 60 years on both sides. Similar studies in the literature also showed a varying presentation. Shalash *et al.*^[15] conducted a study on 120 CBCT scans and found that the MF was present, on average, 10.27 mm above the inferior border of the mandible, with no significant gender difference. In a study done by Kalender *et al.*^[16] examining 386 CBCT scans, MF was found to be 12.4 mm above the lower border, which is more compared to our study.

In the present study, linear regression was also evaluated. With one unit increase in distance from the right side of the MF to the lower border of the mandible, the length of AL increased by 0.136 times, whereas with one unit increase in distance from the left side of the MF to the lower border of the mandible, the length of AL increased by 0.163 times.

Conclusion

The prevalence of AL in this study was relatively higher and the AL prevalence was greater in subjects ranging from 41 to 60 years, with a slight increase in female predominance. The mean length of AL in panoramic and oblique views did not show any statistical variation, but measurement in cross-sectional slices showed a marked difference, which could be attributed to the thickness of the slicing in this method. Length of AL was greater on the right side in males, and on the left side, it was greater in females, with a significant variation in Y-shaped AL noticed more predominantly than in T shape. The distance from the MF to the inferior border of the mandible was greater on the right side than on the left side. In comparison, it was greater in females than in males.

After analyzing the data, it has been concluded that CBCT has emerged as a superior diagnostic modality for the evaluation of AL and thereby is useful in preoperative surgical planning. There are similar studies reported in the literature, but they have been carried out in different geographical areas. The present study depicts the ANL presentation in a South Indian population. The findings of this study support the present recommended surgical considerations. Further studies with a greater sample size would be required in order to make a

strong recommendation with regard to safety margins required in the anterior region of the mandible.

Abstract---Aim: To evaluate the drug volume and onset of action of local anesthetic agent in different bone densities. Methodology: Present study was conducted on 40 subjects (20 male and 20 female) between 25 to 50 years attending to Sibar Institute of Dental Sciences, A 1.8ml 2% lignocaine with adrenalin was injected in the buccal mucosa(1ml) and palatal mucosa (0.8ml) in desired site of evaluation in maxilla. The duration of onset of action in minutes and drug volume used in milliliters was evaluated, where mainly comparison was done between two different densities of bone (D2,D3) according to

Misch classification. Results: Areas of maxillary which had a denser cortical bone (D2) needed more volume (1.8-3.6 ml) of local anaesthetic solution (mean \pm sd= 2.98 \pm 1.02) for achieving its mode of action and subsequently lead to numbness when compared to D3 bone which was more of a porous variety which needed less volume of anaesthetic solution (mean \pm sd= 1.63 \pm 0.78) to achieve results. The comparative result was statistically significant (P=0.037). Conclusion: The denser the bone, more time it would take to achieve adequate level of anesthesia.

Keywords---local anesthesia, cortical bone, infiltration anesthesia.

Introduction

Over the past century, there is perhaps no greater contribution to the practice of clinical dentistry than the development and application of local anaesthesia. What were once considered painful procedures have now been made routine by the deposition and action of local anaesthetics. The majority of commonly used dental local anaesthetics fall into the amide category (lidocaine, mepivacaine, bupivacaine, prilocaine), though there are some amide-type local anaesthetics that also contain an additional ester linkage (articaine). While both types of local anaesthetics have the same mechanism of action, they differ slightly in their metabolism. Intraosseous anaesthesia (IO) allows the anaesthetic solution to be injected directly into the cancellous bone. The anaesthetic solution immediately reaches the periapical region, and thus the axonal area of the nerve, where it can temporarily disable the sodium pump. The anaesthetic effect can be achieved with almost no time lag, and only a small amount of anaesthesia is needed. The transcortical injection technique avoids nerve injuries that are commonly related to the use of intraoral nerve z blocks in cases of symptomatic pulpitis. Accidental vessel injection or lingual nerve injuries can be prevented.¹ The duration of action of a local anaesthetic is contingent on two factors: the protein binding and redistribution of the local anaesthetic. Protein binding of the local anaesthetic is an inherent drug characteristic – the more protein-bound a drug is, the longer the duration of action. Duration of action on dental pulp and soft tissues is contingent almost completely on diffusion away from the site of action of the local anaesthetic. If an area is more vascular, the faster the drug will be absorbed into systemic circulation and away from the target tissue.² Use of local anaesthesia is necessary to achieve an uninterrupted field of operation and necessary for the comfort of the patient. The knowledge of pharmacology is a paramount for safe and optimum use of this group of drugs. There are many factors that influence the mechanism of action of local anaesthetic solution like the type of drug used, volume of solution, bone quality in the area of usage, local condition of tissues, technique of injection etc. Computed tomography (CT) scan has been commonly used for pre-operative quantitative and qualitative assessment of implant sites and is routinely used to determine the bone density (quality) of the bone. It allows precise 3D evaluation of anatomic structures and direct measurement of bone density, expressed in Hounsfield units (HUs).³ HUs are standard numbers originating from CT imaging. HUs represent the relative density of body tissues according to a calibrated gray-level scale, based on values for air (-1000 HU),

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

water (0 HU), and bone density (+1000 HU).^{4,5} Today, CBCT is increasingly substituting multislice CT in dentistry for evaluating mineralized tissues because it provides adequate image quality, associated with a lower exposure dose.⁶⁻⁸ CBCT also offers advantages such as low cost, fast scanning time, and lower number of image artifacts.^{9,10} Over CT, it provides shorter acquisition times, submillimeter resolution, and also delivers good spatial resolution, gray density range, and contrast, as well as a good pixel/noise ratio.^{11,12} The current study focuses on the evaluation of influence of bone quality on onset of action and the volume of anaesthetic solution required.

Aim of the present study

To evaluate the drug volume and onset of action of local anesthetic agent in different bone densities. Correlation with onset of action and drug volume in different bone densities was evaluated.

Methodology

The present study was conducted on 40 subjects (20 male and 20 female) between 25 to 50 years attending to Sibar Institute of Dental Sciences, A 1.8ml 2% lignocaine with adrenalin was injected in the buccal mucosa(1ml) and palatal mucosa (0.8ml) in desired site of evaluation in maxilla. The duration of onset of action in minutes and drug volume used in milliliters was evaluated. Cone beam computed tomography (CBCT) was done to evaluate the quality of bone and the samples was categorized into different qualities. Clinicians were blinded and their opinion on the bone quality. Bone quality was determined according to Misch classification ¹³ (Table 1) Statistical analysis was conducted with the help of SPSS 25.0 from the data obtained from the CBCT values using Kruskal–Wallis test.

Results

It was observed that in maxilla, the areas which had a denser cortical bone (D2) needed more volume (1.8-3.6 ml) of local anaesthetic solution (mean \pm sd= 2.98 \pm 1.02) for achieving its mode of action and subsequently lead to numbness when compared to D3 bone which was more of a porous variety which needed less volume of anaesthetic solution (mean \pm sd= 1.63 \pm 0.78) to achieve results. The comparative result was statistically significant (P=0.037). However, when the time of the onset of anaesthesia was calculated, it was seen that bone which had D3 density achieved faster onset (average =2.8 minutes) as compared to D2 bone, due to more porous and vascular bone in the former which helps the anaesthetic solution to travel faster to the affected area. When the type of tooth which were anesthetized were compared, more volume of solution was needed to achieve the result in anterior teeth (mean \pm sd= 2.157 \pm 1.813) as compared to posterior teeth. The result was not statistically significant (p=1.36). (Table 2)

Discussion

Pain control with irreversible pulpal pain or oral hard and soft tissue pathologies is one of the greatest challenges. Emphasis should be placed on the very precise anaesthetic effect into the jaw, and therefore, a small amount of anaesthetic

solution is needed. This is a benefit, especially for treating patients with risks. A j Certosimo et al., conducted a study on reliability of electric pulp tester on predicting the level of anaesthesia. The study was performed in vivo on patients requiring operative therapy. All teeth were pulp tested preoperatively for vitality using the electric pulp tester. After injection of local anaesthesia, traditional parameters of dental anaesthesia were verified (lip numbness, mucosal sticks). Teeth were then retested with the electric pulp tester and the results recorded and concluded that electric pulp tester is a valuable clinical aid for practicing dentists, which could enable them to objectively monitor the course of anaesthesia prior to the restorative procedure.¹⁴ In a study stated that Hounsfield units (HU) was derived from Grey Scale Values obtained from CBCT, using a mathematical formula ($HU = -61.098 + 1.178 \times GSV$) derived by Razi et al. This can provide the exact bone quality in region required. The estimation of exact bone quality at surgical site can help clinicians, interpret, and plan before commencement of treatment.¹⁵ Farhad et al.¹⁶ included 60 patients and investigated the success rate, effect on blood pressure, and pain relief. After injecting 3% mepivacain, the success rate of pulpal anaesthesia was compared using pulp tests in both groups. The systolic and diastolic blood pressures of the patients were documented before and after injection. The severity of pain during injection was rated using the VAS. The success rate of pain relief of IO during treatment (56.7%) was significantly higher than that of Inferior alveolar nerve block (IANB) (23.3%) ($P = 0.008$). Both techniques showed no significant difference in pain during injection ($P = 0.304$), and systolic ($P = 0.080$) or diastolic ($P = 0.28$) blood pressure after injection. In a commentary of the study by Collier et al., he highlighted that the success rate of IANB as the primary technique for lower molars with irreversible pulpitis was assumed to be 18.9% only¹⁷ and that this may be caused by methodological flaws. This further emphasizes the suitability of the IO as the primary technique for anaesthesia for these teeth. Martinez et al. tested IO in comparison with IANB for hot teeth in the posterior mandibular region.¹⁸ In our study, it was evident that D2 bone which was more denser than the D3 bone, needed more of anaesthetic solution as well as there was increased duration related to onset of action of anaesthesia.

Conclusion

The results of this study will help in assessing the influence of bone quality on onset of action and the volume of anesthetic solution required. The denser the bone, more time it would take to achieve adequate level of anaesthesia.

Evaluation of Immediately Loaded Parallel Conical Connection Implants with Platform Switch in the Maxillary Esthetic Zone: A Prospective Clinical Study

Haripriyanka K Raj¹, T Krishan Mohan², Vivekanand Kattimani³, Raghunadh Sreerama⁴, Yella Ramya⁵, Chaitanya K Inampudi⁶

ABSTRACT

Aim: To assess immediately loaded parallel conical connection (Nobel Biocare) implants with platform switch design in the maxillary esthetic zone for soft and hard tissue changes.

Materials and methods: A total of 20 patients ($n = 20$) underwent prosthetic replacement of the missing maxillary anterior tooth, with an immediately loaded parallel conical connection implant (Noble Biocare, Sweden) having a platform switch design. The size of the implant was 3.75 mm in width and 13 mm in length for all patients and placement followed a standardized surgical protocol. Postoperatively, acrylic provisionalization was done within 48 hours followed by a definitive zirconia prosthesis in the 3rd month. Clinically and radiographically, the implants were evaluated for hard tissue (bone density, implant stability, crestal bone loss) and soft tissue changes (mucosal thickness—MT, sulcus probing depth—PD, bleeding on probing—BOP, width of keratinized gingiva—KG) at baseline till 36 months with follow-up intervals after loading.

Results: All patients showed uneventful healing. The difference in implant stability and density scores was significant ($p < 0.05^*$) from baseline to 36 months indicating bone formation and osseointegration of the implant. Bleeding on probing was not observed, and probing depth remained within the acceptable range (≤ 5 mm) at all time intervals after loading. The marginal bone loss was minimal (≤ 0.2 mm annually) with the absence of implant mobility and without any peri-implant radiolucency. The thickness of the gingiva (3.47 ± 0.34 mm) and width of keratinized gingiva (2.46 ± 0.39 mm) remained within reasonable limits at the 36th month with acceptable esthetic appearance.

Conclusion: In the present study, immediate loading of Nobel parallel conical connection implant in the maxillary anterior region provided adequate primary stability, minimal marginal bone loss, and increased bone density indicating earlier osseointegration. Decreased probing depth, absence of bleeding on probing, and adequate tissue collar at the neck showed better soft tissue emergence in the esthetic zone. The platform switch design demonstrated promising results and therefore can be used as an alternative to the conventional method.

Clinical significance: The present study results suggest that parallel conical connection implants (Nobel Biocare) with TiUnite surface, built-in platform switch combined with conical connection interface, parallel walled body, tapered apex, and double threads from tip to platform are all designed to provide high primary stability and support immediate function protocol, hence can be used flexibly in different bone densities.

Keywords: Esthetics, Immediate loading protocol, Nobel parallel conical connection implant, Platform switch, Prosthesis replacement.

INTRODUCTION

The dentist must use considerable clinical skill to help patients cope with the effects of partial or complete edentulism. Dental implants are assisting in solving more difficult problems of restoration associated with missing teeth. Because of advances in implantology, patients are now enjoying fixed implant rehabilitation with good available bone. Even the patients with a single missing tooth in an esthetic zone can receive a restoration analogous to the missing natural tooth. Per Ingvar Branemark, an orthopedic surgeon in the University of Lund, Sweden, in 1952 experiment showed the fusion of titanium cylinders into the thigh bone of a rabbit, and this phenomenon is known as “osseointegration” that produced a major leap for dental implants. Osseointegration is defined as “a direct structural and functional connection between ordered, living bone and the surface of a load-carrying implant.” Further Branemark followed the orthopedic literature recommendations to place dental implants with primary stability in a submerged fashion to avoid movement during healing. The long-term follow-up study of these implants was first published in 1977 and confirmed that primary stability

and a stress-free healing period were the two main requirements for osseointegration.¹ Several clinicians and scientists published their experience and agreed that the osseointegration requires primary stability and a period of submerged stress-free healing for 3–6 months before loading with the prosthesis. The success rate of 95–99% was observed in edentulous patients that were restored with implant-supported fixed prosthesis after following 6–15 years using this protocol. But, in this two-stage protocol, the waiting period from placement of an implant to loading was long usually 6 months in the maxilla and 3 months in the mandible. So, the functional concerns of patients during this healing period for osseointegration were raised.^{1,2} The paradigm shift in loading of the implant-supported prosthesis from delayed and early loading to immediate loading was initiated in recent years. This shift in the loading protocol is patient-driven. In the recent past, many clinical protocols were limited to provisional restorations that have shortened treatment time for the return to function but the final restoration time remained the same as conventional.³ So, various implant designs have been introduced to meet the immediate loading need. According to the fourth International Team for Implantology (ITI) consensus conference, immediate loading is defined as “dental implants that are connected to the prosthesis within 1 week after the implant placement.” The literature suggests that primary stability is an important parameter to yield proper survival of implants for all placement protocols. Insertion torques ≥ 30 N cm, implant stability quotient (ISQ) ≥ 60 , and minimal implant length ≥ 10 mm with a minimum diameter of 3 mm are recommended if accelerated loading protocols are utilized.⁴ The implant design, abutment interface, and fixation of prosthesis to implant body have changed in recent years to meet the changing clinical scenario to achieve the goal of immediate restoration that can deliver predictable treatment results in the maxillary esthetic zone.

Based on the above-mentioned parameters and guidelines, the present study assessed the immediate loading of parallel connection implants (Nobel Biocare) with platform switch design in the anterior maxilla. The objectives were evaluation of marginal bone loss, implant stability, bone density, sulcus probing depth, mucosal thickness, keratinized gingival width, and bleeding on probing.

PATIENTS AND METHODS

Study Design and Material

The present study was performed in the Department of Prosthodontics, Crown and Bridge, including Implantology during 2017–2021. A total of 20 patients with an age range of 20–45 years of either gender with missing anterior maxillary tooth and willing to take part in the study protocol were enrolled. The protocol was approved by institutional ethics committee.

Inclusion and Exclusion Criteria

- Systemically healthy patients with a history of a missing maxillary anterior tooth not less than 6 months with adequate bone quality and quantity (≥ 6 mm width \times 14 mm height) reluctant for removable or tooth-supported fixed partial dentures were included.
- Patients with a history of head and neck radiation, psychological problems, and parafunctional habits, like clenching, bruxism, deep bite, smoking, tobacco chewing, and alcohol abuse, were not included.

Source of support: Nil

Conflict of interest: None

Method

Treatment planning for implant-supported restoration was done after obtaining thorough medical and dental history followed by clinical and radiographic evaluation of hard and soft tissues for each patient according to a predetermined clinical protocol. Routine blood investigations were performed to rule out any systemic or metabolic diseases. Standard intraoral periapical radiographs (IOPAR) with paralleling technique were obtained using an X-ray grid to evaluate available bone height. A bone caliper was used to assess bone width under local anesthesia. The interarch relationship was assessed using mounted diagnostic casts. Preoperative 3-dimensional cone-beam computed tomography (3D-CBCT) was obtained for further evaluation and surgical planning. A conventional surgical guide using self-cure acrylic was fabricated on study models for each patient (Fig. 1).

Recently introduced parallel conical connection (Nobel Biocare) implants with platform switch measuring 3.75 mm diameter and 13 mm length (Nobel Biocare, Sweden) were placed in all the patients (Figs 2A to C). The implants were loaded immediately on the same day and provisional restoration was given within 48 hours. Each patient was recalled after 3 months for definitive restoration. Clinically and radiographically, the implants were evaluated for hard (bone density, implant stability, crestal bone loss) and soft tissues changes (mucosal thickness—MT, sulcus probing depth—PD, bleeding on probing—BOP, width of keratinized gingiva—KG) at baseline up to 36 months with follow-up intervals after loading. The stability of the implant was assessed using Osstell-resonance frequency analyzer measured in ISQ:1–100. Bone density values were measured using IOPA digital radiographs with Digora software (Fig. 3). Crestal bone loss was measured using standard IOPAR with the help of grids. The distance between the implant shoulder and the alveolar crest was measured at the mesial and distal areas of the implants. Mucosal thickness (MT) was assessed using endodontic file number 20 with a rubber stopper. The file was inserted at the midpoint of the attached gingiva between the mucogingival junction and an imaginary line drawn from adjacent tooth cemento-enamel junction (CEJ) (Fig. 4A). Distance between the

Figs 4A to D: Evaluation of (A) Mucosal thickness using endodontic file number 20; (B) Width of keratinized gingiva using metal scale measured from mucogingival junction to the base of the sulcus; (C) Sulcus probing depth using plastic probe; (D) Bleeding on probing using a pressure-sensitive probe

tip of the file and rubber stopper was recorded as mucosal thickness using a digital caliper (to the nearest 0.1 mm). The width of the keratinized gingiva was measured using William's probe mid-facially

from the gingival margin to the mucogingival junction (1 week after suture removal) (Fig. 4B). Sulcus probing depth (PD) was measured using William's probe (Hu-Friedy Colorvue® probe) at mesial, distal

line angle, and middle of labial/palatal areas (Fig. 4C). Bleeding on probing (BOP) was measured using a pressure-sensitive probe that was passed along the gingival sulcus with a force of 0.25 N and waited for 30 seconds to score the bleeding index (Fig. 4D). The scoring criterion was adopted from the modified sulcular bleeding index by Muhlemann and son: score 0—no bleeding, score 1—pinpoint bleeding, score 2—the thin linear rim of bleeding, and score 3—profuse bleeding. All the radiological parameters were assessed by two observers.

Surgical and Prosthetic Procedure

Under local anesthesia, the thickness of soft tissue was measured at a predetermined point using endodontic file no. 20. One crestal and two vertical relieving incisions were made, and a full-thickness mucoperiosteal flap was reflected to expose the underlying bone.

Point of entry was gained through a surgical guide using a precision drill. Later, sequential drilling was done as per manufacturer instructions (2.0, 2.4/2.8, 2.8/3.2, cortical drill of 3.75 mm, screw tap of 3.75 mm in case of dense bone) with a drilling speed of 800–2000 rpm (Figs 2A to C). A narrow platform implant (NP) was placed slightly below the crestal level (0.5 mm) with a torque of 35 N cm. Primary stability values were checked using a resonance frequency analyzer (Osstell). Implant abutment was fixed, and soft tissue edges were sutured by interrupted sutures using 3-0 Mersilk. Antibiotics, analgesics, and mouthwash were prescribed for all patients.

Primary impressions were made using alginate for the fabrication of provisional crowns (indirect method). Immediately after implant placement, IOPAR with an X-ray grid was taken to assess the bone density and marginal bone level at baseline.

Provisional crown (self-cure acrylic) was cemented with temporary luting cement (Eugenol free Zinc Oxide) after 48 hours, which was replaced by zirconia prosthesis after 3 months. Each patient was given postoperative instructions and recalled after 7 days for suture removal. Later all patients were assessed at follow-up intervals of 3rd, 6th, 9th, 12th, 24th, and 36th months.

Statistical Analysis

The observations were tabulated using Microsoft Excel, and statistical analysis was carried out using the statistical package for social sciences (SPSS Version 26.0) software. Descriptive statistics along with Friedman and Wilcoxon matched-pairs tests were used. The quantitative variables were represented in means and standard deviations. The *p*-value ≤ 0.05 was considered to be statistically significant. The degree of interobserver agreement was assessed using the kappa correlation for radiological assessment.

RESULTS

Clinical Observations

All the patients with a mean age of 32.5 years showed a well-healed wound postimplant placement and loading. The present study included the replacement of missing right central (60%), left central (30%), and left lateral (10%) incisors. Implant stability was increased gradually from baseline (56.96 ± 2.96 ISQ) to 3rd (58.22 ± 2.18 ISQ), 6th (64.66 ± 4.15 ISQ), 9th (64.66 ± 4.15 ISQ), 12th (64.54 ± 4.01 ISQ), 18th (66.54 ± 3.60 ISQ), 24th month (66.92 ± 3.87 ISQ), and 36th month (66.92 ± 3.87 ISQ) (Fig. 5). The mucosal thickness scores at baseline and 3rd month were 3.44 ± 0.35 mm and 3.47 ± 0.34 mm, respectively, and the remaining scores till 36th month were presented in Figure 6. The

Fig. 5: Comparison of mean stability scores from baseline to 36 months with the follow-up intervals

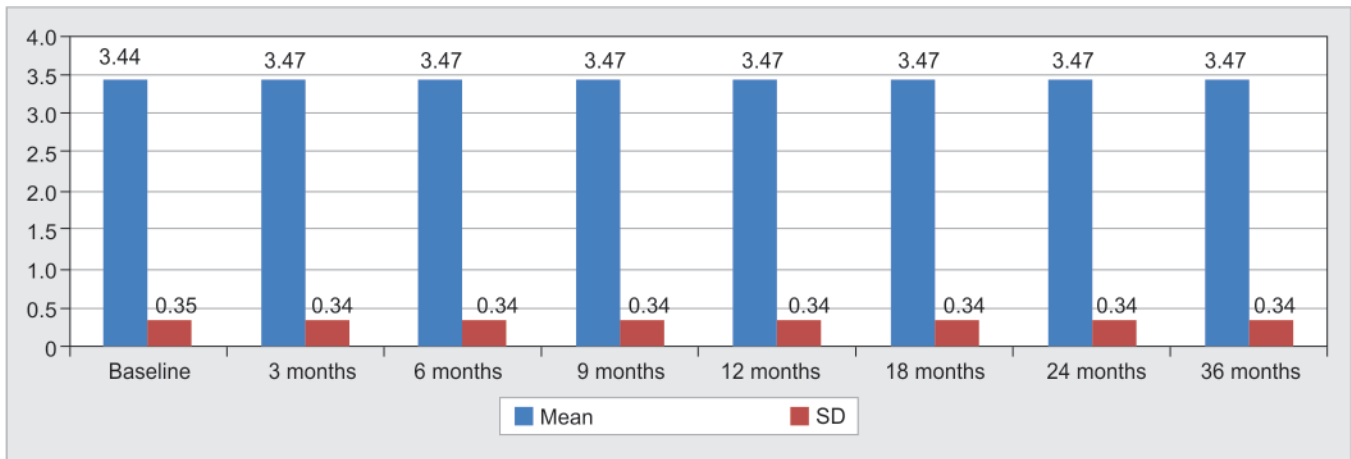

Fig. 6: Comparison of mean mucosal thickness scores from baseline to 36 months with the follow-up intervals

mean width of the gingiva was 4.105 ± 0.476 mm at baseline and was decreased to 2.46 ± 0.39 mm by the 36th month (Table 1). The mean sulcus probing depth was 1.45 ± 0.19 mm at the 3rd month and was decreased to 1.35 ± 0.33 mm at 36th month during the

follow-up period (Fig. 7). The mean rank of bleeding on probing was 3.4 at 3rd month reduced to 2.45 at 36th month during the follow-up period (Table 2). At the end of 36-month follow-up, none of the implants showed clinical signs of failure.

Radiological Observations

Peri-implant density scores were low at 3rd month compared to baseline and 6th month on the mesial side. The density scores were increased at the 6th month (mesial 113.4, distal 123.2) compared to 3rd month (mesial 100.0, distal 107.1) indicating bone formation and osseointegration (Fig. 8) (Supplementary Table 1). Results showed significant difference in bone formation from 12th to 36th month (*p* ≤ 0.05*). Mean crestal bone loss on the mesial and distal side of implant was 0.60 ± 0.29 mm at 3rd month, whereas it was increased to 1.17 ± 0.28 mm on the mesial side and 1.17 ± 0.28 mm on the distal side at 36th month during the follow-up period (Fig. 9) (Supplementary Table 2). The interobserver agreement was found to be good with a kappa value greater than 0.61.

INFERENCE

Clinical and radiological observations of the present study showed a significant increase in the bone density scores and stability values with minimal marginal bone loss, better soft tissue emergence with no bleeding on probing, and adequate keratinized gingiva. Hence, immediate loading of parallel conical connection (Nobel Biocare) implant is favorable in the maxillary esthetic zone with varying densities of alveolar bone.

DISCUSSION

The phase of restorative dentistry has been changed because of implants. The development of implant materials and implant design, with optimized surgical and prosthetic treatment protocols, has opened a wide array of treatment options for clinicians and patients.⁵ Implant-supported restoration provides better functional

stability of the prosthesis, which immensely improved the quality of life in edentulous patients.

Research and treatment evaluations have been shown to optimize the biomechanical design of superstructures and selection of patients for different treatment protocols, making oral implantology an even more predictable treatment option. Innovation, knowledge, and experience have led to improved implant designs and optimized treatment protocols.⁶ Thorough understanding of bone biology is an essential factor for adopting the proper treatment protocol.⁷ Different loading protocols have been proposed since the beginning of implant dentistry (Branemark Era). The changing scenario and patient's need for an immediate solution led to immediate loading protocols for the replacement of missing teeth. Immediate loading refers to an abutment connection and placement of restoration in occlusion at the time of surgery or within 48 hours.⁸ Better understanding of micromotion led to the development and evolution of the concept of immediate loading.⁹ A perceived psychological, economic, and functional advantage of shortened treatment periods has encouraged clinicians to challenge the conventional restoration with immediate temporization and/or early loading of dental implants.² So, the present study planned to assess hard and soft tissue changes after immediate loading of parallel conical connection (Nobel Biocare) implant with platform switch design for the restoration of single missing tooth in maxillary esthetic zone.

In the present study, stability of the implant was assessed using Osstell-resonance frequency analyzer (Osstell; Goteborg, Sweden) by attaching a standard transducer to the implant, immediately after implant placement and was repeated at follow-up intervals. All the implants showed mean primary stability values of 56.96 ± 2.96 ISQ which was significantly increased from baseline to 36 months indicating optimal osteointegration of the implant. In the present

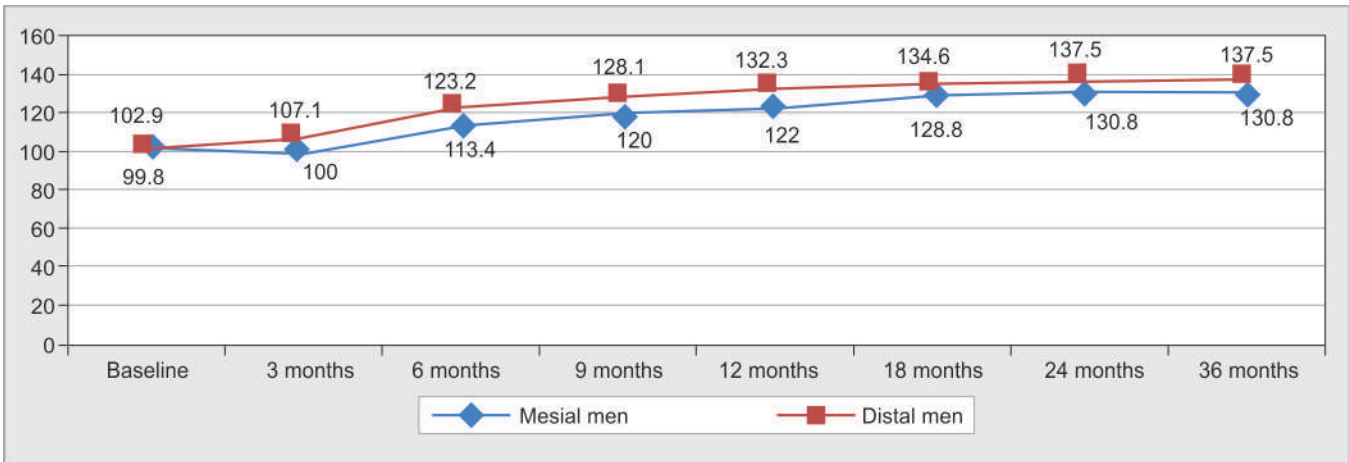

Fig. 8: Comparison of mean mesial and distal bone density scores from baseline to 36 months with the follow-up intervals

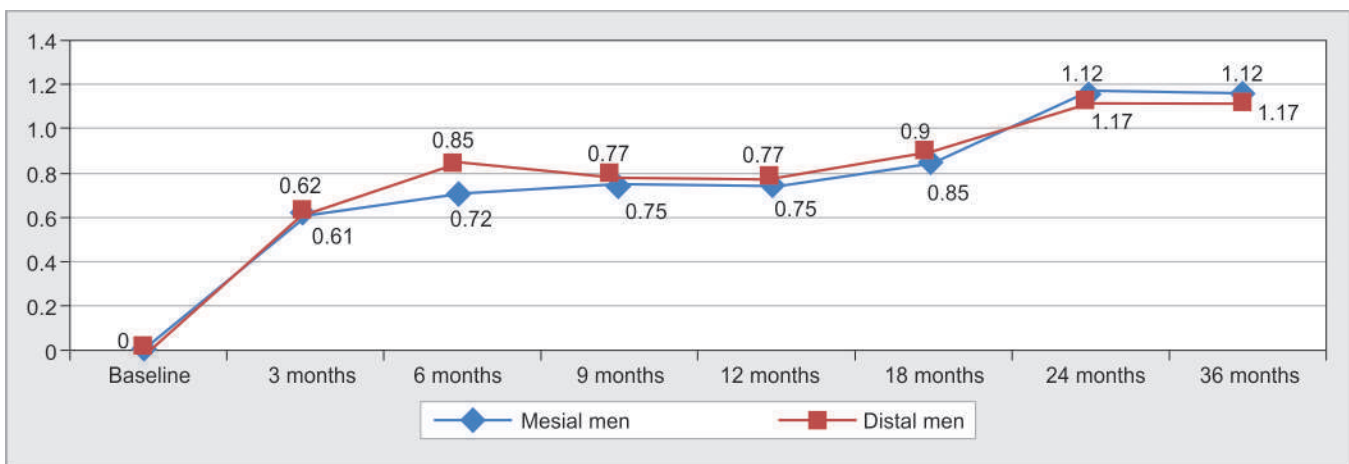

Fig. 9: Comparison of mean mesial and distal crestal bone loss scores from baseline to 36 months with the follow-up intervals

study, no mobility was observed indicating a 100% survival rate. This observation is in accordance with the study of Lorenzoni et al. indicating successful osseointegration.¹⁰ The resonance frequency analyzer findings of Fischer et al.¹¹ study showed little higher values than the present study at baseline (63.3 ± 6.1 ISQ) and 3rd month (64.3 ± 5.3 ISQ) whereas 6th-month values were similar (65.0 ± 4.6 ISQ). But these values were not from a single site and also Fischer et al.¹¹ have not standardized the implant size. But in the present study, implant size was standardized (3.75 mm diameter, 13 mm length) to overcome the bias associated with the length and diameter of the implant.

Peri-implant bone density values were measured using digital IOPAR with Digora software at baseline, thereafter at various follow-up time intervals till 36 months. Digora software measures density with a range of 0–255 pixels using the density tool. Mean bone density on the mesial side of the implant was decreased from baseline (102.90 ± 27.48) to 3rd month (100 ± 27.95) indicating early bone modulation, whereas on the distal side, (107.1 ± 41.12) it is increased. These changes were statistically insignificant. Later, at 36th-month density values had increased significantly (mesial 130.8 ± 18.9 , distal 137.5 ± 30.94) compared to 3rd and 6th months indicating increased bone mineralization and osteointegration. The density values were well correlated with the stability of the implant.

The crestal bone loss was measured using standard IOPAR with the help of an X-ray Grid. The X-ray Grid consists of one-millimeter graduations superimposed on IOPAR and was used for assessment. Crestal bone loss is an essential criterion for the evaluation of implant success. Schincaglia et al.¹² study showed an average radiographic change in bone level of 0.77 ± 0.38 mm in the immediate loading group and correlated these results to a hypothesis that micromovements caused by immediate loading have a positive effect on osteodeposition. This micromotion-assisted osteodeposition was earlier proved in an animal study by Vandamme et al.¹³ in which the results showed an increase of bone mineralization was significant around immediately loaded implants compared to unloaded implants. Salvi et al.¹⁴ showed 0.57 ± 0.49 mm of bone loss in an immediately loaded group whereas Kim et al.¹⁵ observed bone loss of 0.29 ± 0.19 mm after 6 months of crown placement. But in the present study, after the 3rd month of loading, the mean value of bone loss on the mesial and distal side was same (0.60 ± 0.29 mm). The differential measurements similar to the present study were not available for comparison in the published literature.

Further, mean bone loss of 1.17 ± 0.28 and 1.12 ± 0.27 mm on mesial and distal sides was observed, respectively, after 36 months of loading. These results were supported by the observations of

Schincaglia et al.,¹² Salvi,¹⁴ and Kim et al.¹⁵ The changes observed at 3rd and 36th months on both the mesial and distal sides were statistically significant ($p = 0.000$).

The soft tissue biotype surrounding the implant is one of the essential factors in the esthetic zone. The success of an implant depends on lesser biological complications, like peri-implantitis and gingival recession, which are crucial for aesthetic considerations. Patients with thin, highly scalloped gingiva are at risk of recession. So, it is advisable to ensure an adequate width of keratinized gingiva in the esthetic zone. The primary difference between the implant and tooth lies in the insertion of connective tissue at the neck of the implant (subcrestal in implant and supracrestal in the natural tooth).¹⁶ The present study showed an adequate width of gingiva at baseline and even during the follow-up period of 36 months. Minimal/no keratinized gingiva is still controversial for the development of peri-implantitis.¹⁷ But, published literature showed contrast reports regarding the width of keratinized gingiva and concluded that the width of keratinized gingiva has no role on the survival of the implant.^{18,19}

Mucosal thickness (MT) was measured using endodontic file number 20 with a rubber stopper. The file was inserted at a predetermined reference point. The distance between the rubber stopper and tip of the file was recorded using a digital caliper (to the nearest 0.1 mm) as mucosal thickness. The mucosal thickness in the present study at baseline was 3.44 ± 0.35 mm, whereas at 36th month, it is 3.47 ± 0.34 mm. Results showed no significant changes associated with mucosal thickness throughout the follow-up period with a $p = 0.343$.

The width of keratinized gingiva is measured using William's probe mid-facially from the mucogingival junction of the implant to the free gingival margin. The width of the attached gingiva is defined as the "portion of gingiva that extends from the base of the gingival crevice to the mucogingival junction." It is firm, resilient, and tightly bound to the underlying periosteum, through connective tissue. The presence of an adequate zone of gingiva is considered critical for the maintenance of marginal tissue health and the prevention of continuous loss of connective tissue attachment.^{20,21} Lang and Loe suggested that at least 2 mm of keratinized gingiva with 1 mm attached gingiva is adequate to maintain gingival health.²² Schrott et al.²³ studies showed that patients having good oral hygiene with keratinized tissues of less than 2 mm were not affected on the buccal side, but lingual sites demonstrated peri-implant inflammation because of difficulty in plaque control. However, recent evidence shows the opposite trend.²⁴⁻²⁶ The retrospective studies have shown an association of keratinized mucosa with peri-implant soft tissue health and stability.²⁴⁻²⁶

In the present study, no augmentation procedures were performed as the patients had an adequate width and thickness of gingiva. The width of keratinized gingiva in the present study remained the same over the 6-month follow-up. At baseline, width of keratinized gingiva was 4.105 ± 0.476 mm and is reduced to 2.46 ± 0.39 mm in the 36th month. The reduction is because of increased probing depth in few cases. Overall, the width of keratinized gingiva is within the limits of recommended minimum width. The change in the width might be attributed to patient oral hygiene factors.

In the present study, sulcus probing depth is measured using William's probe on mesial, distal line angle, and middle of buccal/lingual areas around the implant. The probing depth and radiographic measurements were considered for comprehensive

assessment of implant success as suggested by Degidi et al.²⁷ Giovanni et al.¹² study found a mean probing depth of 2.6 mm after 6 months of restoration in the immediate loading group, whereas Heydenrijk et al.²⁸ showed decreased mean probing depth from 3.6 mm (at first month) to 3.3 mm (at 6 months) in the immediate loading group. But in the present study, results showed 1.35 ± 0.34 mm of pocket depth which is lesser than Heydenrijk et al.²⁸ findings. This result substantiates the hypothesis of Schincaglia et al.¹² that osteodeposition is induced by mechanical strain in immediate loading compared to conventional, which led to reduced probing depth and radiographic changes in the bone level ($p < 0.05^*$).

In the present study, bleeding on probing was measured using pressure-sensitive probe at various follow-up intervals with a force of 0.25 N and scored as per the scoring criteria of modified sulcular bleeding index by Muhlemann and son. According to Lekholm et al.,²⁹ bleeding on probing is an earlier sign of inflammation and it may occur concurrently with increased probing depth and radiographic bone loss.³⁰ Salvi et al.¹⁴ observed 9.7% BOP in immediate loading group. In the present study, two patients showed bleeding on probing in the 3rd month which might be attributed to poor oral hygiene, and the count was decreased to one patient at 6th-month follow-up. Decrease in BOP might be attributed to effective oral hygiene instruction followed by the patients, and these results are in accordance with Salvi et al.¹⁴

Peri-implant radiolucency is defined as "radiographic evidence of progressive peri-implant bone loss." In the present study, peri-implant radiolucency is within the acceptable range (≤ 0.2 mm annually) and is in accordance with Degidi et al.²⁷ observations. The present study showed a 100% survival rate after 36 months of loading according to the success criteria of Albrektsson et al.¹⁹

In the present study, one patient showed BOP and was advised to follow strict oral hygiene instructions. Probing depth associated with peri-implant health in the present study remained within the normal limits ≤ 5.0 mm after 36 months of loading. The success of immediate loading requires careful and strict patient selection criteria aimed at achieving good primary stability, avoiding any excessive functional or non-functional loading.¹⁰

Studies indicate that ISQ values ≥ 60 demonstrated adequate primary stability where immediate loading is possible. Whereas ISQ values falling between 40 and 50 has to go for delayed loading and ISQ values less than 40 indicate potential risk of implant failure.³¹ But the present study showed primary stability of 56.96 ± 2.96 ISQ and is very near to the published literature value.³² Jawbone quality and primary implant stability are important prerequisites for a successful treatment outcome. In the present study, we considered ISQ values of more than 50 and insertion torque of more than 35 N/cm for immediate loading of the implant.

In the present study, a parallel conical connection implant (Nobel Biocare) with a unique TiUnite surface with grooves was used that maintained implant stability by faster bone formation that promoted long-term success. The combination of controlled titanium oxide texture and porosity makes bone growth onto the surface and into the grooves of implant threads.³³⁻³⁶ The application of immediate loading protocol is beneficial and is an alternative option to conventional loading for optimizing osseointegration, higher acceptance, patient satisfaction, and reduced treatment time. However, success is attributed to factors such as primary stability, marginal bone loss, implant design, osteotomy, and quality of the bone.³⁷

The parallel conical connection system has a limited number of drills that ensure straightforward surgical protocol and can be used flexibly in different bone densities. The design of the implant provides high primary stability and support for the immediate function/loading.^{38,39} The apex design allows bicortical anchorage to obtain high primary stability.⁴⁰ The design of the implant-abutment interface is an important factor as it provides a favorable connection for the growth of the gingival band around the abutment or neck of the implant. So platform switch has a unique advantage of better soft tissue adaptation around the implant neck and is essential in esthetic zone restorations. The recently introduced parallel conical connection (Nobel Biocare) implant with a platform switch offers a better clinical advantage over the conventional design.

LIMITATIONS

The results were obtained after 36 months of follow-up with a smaller sample size. The long-term studies with a large sample size are recommended for the predictability of success rate conclusively. The present study warrants multicenter studies using cone-beam computed tomographic evaluation based on bone density classification to provide guidelines for clinicians apart from ISQ or torque values for loading.

CONCLUSION

The present study showed promising results with 3-year follow-up duration. Marginal bone loss was minimal. Sulcus depth and bleeding on probing were confined to normal physiological limits indicating adequate soft tissue collar formation due to platform switch design. Increased bone density without any periapical or peri-implant radiolucency indicated 100% implant survival showing better osseointegration.

Author Contributions

HPK and TKM were involved in the planning, conceptualization, and investigation of the study. HPK, VSK, and RS carried out the data collection, analysis, and thesis write-up. HPK, TKM, YR, and CKI were responsible for the data analysis, photographs, and final reading approval.

ACKNOWLEDGMENTS

Authors would like to thank the Principal, other colleagues of Department of Radiology, Department Oral and Maxillofacial Surgery, Registrar and Vice-chancellor for permitting to carry the research as a part of the dissertation work.

Abstract

Introduction: In the quest of articulating customized tobacco cessation strategies, evaluation of the level of nicotine dependence among participants is quintessential. **Objective:** This study was conducted to assess the levels of nicotine dependence and its association with age and socioeconomic status among patients seeking oral health care at a teaching dental institution in coastal Andhra Pradesh. **Materials and Methods:** This cross-sectional study was done among 199 participants with the habit of cigarette smoking who participated in the study. Nicotine dependence scores were assessed using Fagerström Test for Nicotine Dependence (FTND). IBM SPSS version 20 software was used for data analysis. The Chi-square tests and Kruskal–Wallis analyses of variance were done to analyze the study data. $P \leq 0.05$ was considered statistically significant. **Results:** The mean FTND score was 4.52 ± 2.1 . Significant differences in the mean nicotine dependence score were found between different age groups ($P < 0.001$) and participants belonging to different socioeconomic strata ($P < 0.001$). While a positive correlation was observed between age and FTND score, an inverse relation was noted between FTND score and socioeconomic status with participants from lower socioeconomic status demonstrating higher FTND scores. The majority of the participants reported smoking < 10 cigarettes per day. **Conclusion:** The study participants demonstrated moderate nicotine dependence. The assessment of nicotine dependence scores as a preliminary step in tobacco cessation counseling is essential to effectively articulate customized cessation strategies.

Keywords: Fagerström scale, nicotine dependence, smokers

INTRODUCTION

Tobacco consumption emerged as one of the most common and deleterious habits in recent decades.^[1] The global statistics reveal the ubiquitous nature of tobacco use.^[2] In India, the habit of tobacco consumption is very prevalent with 28.6% of all adults consuming tobacco in one form or the other.^[3] The contribution of tobacco toward a country's disease burden and the range of negative health outcomes tobacco could be responsible for led to the identification of tobacco consumption as a global epidemic.^[4] In the Indian context, a lot of efforts have been directed toward making people aware of the ill effects of tobacco. The Indian government has been making consistent efforts to bring down the growing consumption of tobacco which include the Cigarette Act 1975 and Cigarettes

and Other Tobacco Products Act, 2003. In 2007, National Tobacco Control Programme was launched and the National Tobacco Control Cell was constituted which organizes at the national, state, and district levels.^[5]

Although oral health-care professionals are well informed about the scope of the dental profession in identifying tobacco users and offering tobacco cessation counseling, it is seldom considered an integral part of the provision of oral health

Assessment of nicotine dependence among cigarette smokers seeking oral health care using fagerström test for nicotine dependence: A cross-sectional study. J Indian Assoc Public Health Dent 2022;20:388-92.

therapy at the dental office are evolving to be an effective means of achieving tobacco cessation among patients.^[7,8] These strategies not only provide the tobacco users with information about the quit process but also attempt to identify reasonable ways to identify motivational cues from previous quit attempts of the participants and draft customized strategies to counter the circumstances that preclude cessation of tobacco use.^[9] However, in the quest of articulating customized tobacco cessation strategies, evaluation of the level of nicotine dependence among participants is quintessential. The evaluation of nicotine dependence can be done in a multitude of ways which include the Diagnostic and Statistical Manual-IV substance dependence structured interviews,^[10] Fagerström Tolerance Questionnaire^[11] which is an eight-item scale, and the Fagerström Test for Nicotine Dependence (FTND)^[12] which is a six-item scale. There is a paucity of literature on the evaluation of nicotine dependence as a preliminary step in the provision of tobacco cessation counseling. With this background, the objective of this study was to evaluate nicotine dependence among cigarette-smoking dental patients using FTND.

MATERIALS AND METHODS

This cross-sectional study was conducted in a teaching dental institution in coastal Andhra Pradesh. The study was conducted from January 2017 to December 2017. Ethical approval for the study (SJDC/CEC/2015-2016) was obtained from the Institutional Ethical Committee of St. Joseph Dental College, Eluru, on December 22, 2015. Prior permission was obtained from the administrative authorities of the institution before the conduct of the study. The sample size for the study was determined to be 199 using G* power 3.1.9.2 software, (Kiel, Germany: Kiel University)^[13] (Test family: *t*-tests; Test: Means – difference from constant (one sample case); Tails: Two-tailed; α error probability – 0.05; power – 0.8; effect size – 0.2). One hundred and ninety-nine cigarette smokers were recruited for the study. All the participants were self-reported current cigarette smokers (participants who reported smoking at least 100 cigarettes during their lifetime and currently smoking) with no tobacco chewing habits. Informed consent was signed by all the study participants and the data collection was anonymous.

FTND is a six-item scale. Four items in the scale are dichotomous in nature, whereas the other two items are multichotomous. The scale score ranges between 0 and 10 with higher scores indicative of high nicotine dependence.^[12] The test was administered to all the study participants by a single trained interviewer. Details relating to age, gender, education, occupation of the head of the family, and monthly family income were also obtained from the study participants. Socioeconomic status was assessed using the modified Kuppuswamy scale.^[14] Data collection for each participant lasted for 3 min on average. The collected data were later intended to be used to articulate customized cessation strategies

of the institution. Statistical analysis was performed using Statistical Package for the Social Sciences (SPSS) version 22 software (IBM SPSS, IBM, Armonk, NY, USA). Descriptive statistics, Chi-square tests, and Kruskal–Wallis analyses of variance were done to analyze the study data.

RESULTS

The mean age of the study participants was 42.89 ± 17.97 years and all the participants were males. Table 1 presents the age group-wise distribution of the participants' responses to each of the six items in the FTND. It was observed that participants who were 65 years and older prefer to smoke within 5 min after waking up in the morning at a comparatively higher frequency than the younger age groups. Although it was observed that the difficulty to refrain from smoking at forbidden places increased with increasing age, this difference between age groups was not statistically significant. The first cigarette in the morning was reported to be the most difficult one to give up by participants belonging to all the age groups considered in this study except ≤ 24 years. Most of the participants reported smoking 10 or lesser number of cigarettes per day. Among participants who were older than 64 years of age, 48.5% smoked 11–20 cigarettes per day. With increasing age, there was a clear transition from smoking cigarettes during the rest of the day to predominantly smoking in the 1st h after waking up in the morning. The majority of the participants reported that they would not smoke if they were so ill that they were on bed for most of the day.

The mean nicotine dependence score of the study sample was 4.52 ± 2.1 . Table 2 shows the differences in mean nicotine dependence scores based on the age group of the study participants. The highest mean scores were observed among participants aged 65 years and older. When the nicotine dependence scores were compared between participants belonging to different socioeconomic strata, a decreasing trend was observed from lower socioeconomic status to upper-middle socioeconomic status [Table 3].

DISCUSSION

The mean nicotine dependence score observed in this study reveals that there was moderate nicotine dependency among the study participants. To the best of our knowledge, this is the first study to preliminarily assess nicotine dependence scores in the quest of providing tobacco cessation counseling in the tobacco cessation clinics set up in teaching dental institutions as directed by the Ministry of Health and Family Welfare (MOHFW) and the Dental Council of India (DCI).^[15] Cigarette smoking is responsible for chronic diseases like lung cancer that tend to manifest in the later part of life besides compromising the quality of life owing to the other adverse effects on health in the short run. While the immediate impact of cigarette smoking on health is not life-threatening, the chronic conditions developed as a result of the habit can be fatal.^[16-18]

Table 1: Age group-wise distribution of item responses in the Fagerstrom test for nicotine dependence

Item	Category	Age group (years)						P
		≤24, n (%)	25-34, n (%)	35-44, n (%)	45-54, n (%)	55-64, n (%)	>64, n (%)

The mean age of the participants in this study was comparable to the mean age reported in the studies conducted by Farooq *et al.*^[19] and Evins *et al.*^[20] All the study participants were males which is similar to other tobacco-related studies conducted by Farooq *et al.*,^[19] Park *et al.*,^[21] and Hill *et al.*^[22] While moderate nicotine dependency was identified in the present study, another study conducted by Goyal *et al.*^[23] among participants

attending dental outreach programs reported low nicotine dependency. Similarly, a study conducted by Chhabra *et al.*^[24] among patients attending a teaching dental institution reported low tobacco dependency. The mean FTND scores similar to those observed in this study were reported by Webb *et al.*^[25] and Malhi *et al.*^[26] Nearly, 64% of the study participants reported smoking <10 cigarettes per day in this study, which is in contrast with the study conducted by Raja *et al.*,^[27] where only 10% of the study participants smoked <10 cigarettes per day and another study conducted by Farooq *et al.*,^[19] where 75% of the participants reported smoking <10 cigarettes per day.

Participants from lower socioeconomic status were found to have higher FTND scores in the present study which is similar to the findings reported by Chen *et al.*^[28] and Siahpush *et al.*^[29] However, contrasting findings were observed in the study conducted by Ayo-Yusuf and Omole^[30] among adult smokers in South Africa. The possible reasons for higher dependence among participants from lower socioeconomic strata are low self-efficacy among participants and lack of intention to quit the habit which could be due to the stress arising from their social and financial disadvantages. A significant increase in FTND scores was observed with increasing age in this study. Li *et al.*^[31] reported increased dependence scores among middle-aged adults (45–64 years) compared to younger adults and older people. While the exact mechanism for increasing trend in nicotine dependence with increasing age is not completely discernible, it is postulated that desensitization of nicotine cholinergic receptors as a result of prolonged nicotine exposure with increasing age could be one of the primary reasons for this phenomenon.^[32] Furthermore, it is hypothesized that younger individuals are not as vulnerable as their older counterparts in responding to the psychological cues of the urge to smoke.^[33] The limitations of the present

the study results demonstrate that there is moderate tobacco dependency among cigarette smoking participants availing oral health care at dental institutions. Future studies can focus on obtaining data relating to dependency on smokeless tobacco in tandem with cigarette smoking.

CONCLUSION

The findings of this study provide an insight into the fact that there is moderate nicotine dependence among cigarette smokers availing care at oral health facilities, which is high among lower socioeconomic strata and older age groups. Therefore, the establishment of tobacco cessation centers in teaching dental institutions as directed by MOHFW and DCI, and making committed efforts toward drafting and delivering customized tobacco cessation strategies could be very effective.

Evidence of improved bond strength of resin-based sealer with the use of natural antioxidants on hypochlorite treated dentin: an *in vitro* study

Mayana Aameena Banu, Tammineedi Sravanthi, Nagesh Bolla, Sayesh Vemuri, Ram Chowdary Basam, Roopadevi Garlapati, Ram Sunil Chukka

Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur, India

Abstract

Aim. To evaluate the effect of natural antioxidants as final irrigants on the push-out bond strength of epoxy resin-based sealer to the hypochlorite treated dentin.

Methods. Eighty single-rooted human mandibular incisors were prepared using ProTaper Gold (Dentsply, TN, USA) and an irrigation protocol including 3% NaOCl, followed by ethylenediaminetetraacetic acid (EDTA), and 3% NaOCl. The groups (n =20) were divided according to the final irrigant used: Group 1: None (Control); Group 2: 5% sodium ascorbate, Group 3: 5% grape seed extract (GSE); and Group 4: 5% pine bark extract. The obturation of root canals was performed using gutta-percha and AH Plus (Dentsply DeTrey, Germany). Bond strength was evaluated using the push-out test under the universal testing machine at a crosshead speed of 0.5 mm/min, and statistical analyses were performed using one-way ANOVA. The p-value significance was evaluated by Tukey's post hoc test (p<0.01).

Results. Mean push-out bond strength values were compared in all the groups, and there was a statistically significant improvement in the experimental final irrigating groups. 5% pine bark extract had improved bond strength than the other groups, and the least bond strength was observed in the control group.

Conclusion. The irrigation protocols and naturally derived antioxidants affected the resin-based sealer's bond strength to root dentin. It was observed that the use of antioxidants effectively reversed the compromised bond strength of resin-based sealers to root dentin. 5% pine bark extract application showed better bond strength.

Keywords: antioxidant, epoxy resin-based sealers, grape seed extract, pine bark extract, sodium ascorbate

Introduction

Endodontic therapy success depends on the canal disinfection using proper irrigation solutions and subsequent fluid-tight seal between the obturation material and the root dentin. AH Plus is a hydrophobic, epoxy resin-based sealer that is widely used because of its physical properties [1]. The adhesive property of AH Plus to root dentin depends on covalent bonding between the exposed side-chain amine groups and the open

epoxide ring of the collagen network [2]. Dentin surface treated with different irrigation protocols predominantly causes alteration to dentin's collagen fibrils; this may compromise endodontic sealers' adhesiveness to the dentin surfaces [3].

AH Plus can bond to the organic components, principally the collagen network, of root dentin. An irrigation protocol using NaOCl as the final irrigant significantly reduced the bond strength of AH Plus to root dentin (Neelakantan et

DOI: 10.15386/mpr-2014

al.) [4]. Many other studies have demonstrated that the commonly used irrigating solution NaOCl reduces the bond strength between adhesive materials and dentin [5]. Moreover, it potentially reduces the bond strength of the AH Plus sealer. This may be attributed to residual oxygen species' presence on the dentin, which affects the adhesive material's setting time [6].

The compromised bond strength of NaOCl-treated dentin might be restored by applying antioxidants before the adhesive procedure [7]. These agents interact with the by-products of NaOCl, resulting in the reversal of the oxidizing effects of NaOCl and neutralization of the dentin surface [5-7].

However, Erhardt et al. [8] reported that some materials benefited from its protective effects, whereas others yielded negligible results. Naturally derived oxidizing agents can chemically modify collagen without damaging biological tissues and improve dentin matrix properties [9].

The aim of the study is to evaluate the effect of 5% sodium ascorbate (SA), 5% grape seed extract (GSE), and 5% pine bark extract (PBE) on the push-out bond strength of epoxy resin sealer to hypochlorite treated root dentin. The null hypothesis is that antioxidants, as a final irrigant, would not reverse the compromised bond strength of epoxy resin-based sealer and root dentin caused by NaOCl.

Methods

Specimen preparation

After obtaining ethical clearance from the institutional Review Board (238/IRB/SIBAR/2020), eighty non-carious permanent human mandibular incisors extracted due to periodontal reasons with fully developed root apices were selected. All the samples were investigated for the root canal morphology, and teeth with a single canal were included in the study. Each sample was decoronated at the level of cemento-enamel junction perpendicular to the tooth's long axis using a diamond disc at a low speed along with water coolant. The root lengths were standardized to 15 mm. Working length (WL) was established with a size 10 K-file and was set at 1 mm from the apex. A #25 K-file was used to standardize the foramina size. The roots were mounted on the self-cure acrylic resin.

Root canal preparation

ProTaper gold instruments (Dentsply Tulsa Dental Specialties, Johnson City, TN, USA) were used in a 16:1 gear handpiece and torque-controlled electric motor (X-Smart Plus; Dentsply). According to the manufacturer's instructions, a consistent rotation speed of 300 rpm was used in a crown-down manner involving a gentle in-and-out motion. Initially, the orifice was enlarged using orifice opener SX. A shaping file (S1) was passed apically within 2 mm of the working length. Later S1 and S2 files were used till the full working length.

The finishing of the apical one third was done by passing the F1 and F2 till the entire working length was reached. Pecking motion was used for instrumentation, and flutes were regularly cleaned to remove debris.

Irrigation protocol

The irrigation protocols used for all the groups were:

1. 2 ml of 3% NaOCl (prime dental products Pvt Ltd, Maharashtra, India) after each instrument change.
2. Irrigation using 2 ml of 17% EDTA (MD-Cleanser, META Biomed, Korea) in all groups.
3. 1 ml of 0.9% of saline solution.
4. Irrigation for 3 minutes using 5ml of NaOCl and experimental antioxidant solutions as final irrigation.

The root samples were divided into four groups ($n = 20$ each) according to the final irrigation solution.

Group 1: None (Control).

Group 2: 5 ml of 5% sodium ascorbate solution.

Group 3: 5 ml of 5% of grape seed extract solution.

Group 4: 5 ml of 5% of pine bark extract solution.

Preparation of solutions

1.5% sodium ascorbate solution.

5 g of sodium ascorbate (All pure organics, India) was dissolved in 100 ml of distilled water to make a 5% sodium ascorbate solution.

2.5% grape seed extract solution.

5 g of grape seed extract (All pure organics, India) was dissolved in 100 ml of distilled water to make a 5% grape seed extract solution.

3.5% pine bark extract solution.

5 g of pine bark extract (All pure organics, India) was dissolved in 100 ml of distilled water to make a 5% pine bark extract solution.

Root filling procedures

The samples were dried using 25 size paper points (Dentsply Konstanz, Germany). After root canal preparation, all samples were obturated using the single cone technique with 25/.06 gutta-percha points (Dentsply Konstanz, Germany) and AH Plus sealer (Dentsply DeTrey, Konstanz, Germany) according to the manufacturer's instructions. The obturating material was allowed to set for 2 weeks.

Push-out test

A 2 mm slice was obtained from the middle third of the root using a microtome from each root. The push-out test was evaluated by applying a load at 0.5 mm/min, which was applied in an apical to coronal direction until the root filling was dislodged from the root slice. The push-out bond strength was measured under a universal testing machine (Instron Corp, Norwood, MA, USA).

Statistical analysis

The obtained results were statistically analyzed using computer software SPSS version 21.0. One-way analysis of variance (ANOVA) followed by Mann Tukey's Post hoc test was used to analyze the data. Significance was established at $p < 0.01$ level.

Table I. Comparison of mean push-out bond strength of different groups (MPa) using a one-way ANOVA test and Tukey's post hoc test.

Group	N	Minimum	Maximum	Mean	SD	Comparison	p-value
Group-1 (Control)	20	18.809	44.666	31.761	8.334	G-1 VS G-3, G-4	p<0.01*
Group-2 (SA)	20	32.142	45.762	41.116	4.203	G-2 VS G-1	p<0.05*
Group-3 (GSE)	20	31.843	54.456	42.251	8.077	G-3 VS G-4	p<0.05*
Group-4 (PBE)	20	41.559	60.929	51.572	6.452	G-4 VS G-2	p<0.01*

* P- value significant, SD- Standard deviation, N- no of samples.

Results

The one-way ANOVA revealed that the push-out bond strength was significantly affected by antioxidants as final irrigating solutions ($p<0.01$). The mean push-out bond strength values, standard deviation, and p-value significance are shown in table I and figure 1.

Figure 1. Graph representing the comparison of mean push-out bond strength among the groups (MPa).

When comparing the groups, Group 4 pine bark extract showed a statistically significant highest push-out bond strength compared to all other groups. The mean push-out bond strength value of Group 3 was statistically significant with that of Group 4 ($p<0.05$) and Group 1 ($p<0.01$) but not with that of Group 2 ($p>0.05$). The mean push-out bond strength value of Group 2 was statistically significant with that of Group 4 ($p<0.01$) and Group 1 ($p<0.05$) but not with that of Group 3 ($p>0.05$). Group 1 showed the least mean push-out bond strength values than all other groups and was statistically significant ($p<0.01$).

Discussion

Failure in the endodontic therapy occurs due to inadequate fluid-tight seal between the obturating material and the root dentin. Microleakage occurs due to bond failure between the epoxy resin-based sealer and the root dentin. Several studies described the adverse effects of NaOCl on dentin, which includes promoting structural changes in organic dentin components (mainly collagen) [10], and its impact on the mechanical properties, such as reducing the flexural strength and elastic modulus of dentin [11]. Similar reduction in the AH Plus sealer bond strength was

observed in Group 1 of the present study, which may be attributable to the release of residual oxygen species from NaOCl on the root dentin [6]. To overcome this problem, different techniques have been proposed to treat root dentin [12]. Antioxidants such as sodium ascorbate (SA) and oligomeric proanthocyanidin complexes (OPC) have been demonstrated to reverse oxidants' adverse effects and preserve resin-dentin bond integrity.

SA is a biocompatible and nontoxic antioxidant (salt of ascorbic acid-vitamin C) able to reduce a wide variety of oxidizing compounds, mainly free radicals [13]. In the present study, SA (Group 2) showed statistical significance compared to the control group. SA solution reduces the residual free radicals from the interior of the dentinal tubules [14] and dentin matrix [15]. SA reverses the denaturing effect of acid etching, NaOCl, or H_2O_2 on dentin collagen. It is a potent inhibitor of matrix metalloproteinases (MMPs). Hence, it protects against the long-term degradation of the resin-based materials and dentin interface [16]. Khoroushi et al. [17] also indicated that the treatment with SA solution improved the bond strength of fiber posts to dentin.

Group 2 specimens could not reverse the push-out bond strength as much as that of Group 4, which was in accordance with the studies that confirmed the antioxidant potential and the free radical scavenging ability of OPCs are 20 times greater than those of vitamin E and 50 times greater than those of vitamin C (Fine AM [18] and Stokes et al. [19]).

OPCs exhibited 78-81% inhibition of superoxide anion and hydroxyl radical. Under similar conditions, vitamin C inhibited these two oxygen free radicals by approximately 12-19%, while Vitamin E inhibited the two radicals by 36-44% (Bagchi et al. [20]). OPCs present in natural antioxidants like grape seed extract and pine bark extract have free radical scavenging activity [21]. OPCs are a class of polyphenolic bioflavonoids most commonly found in fruits and vegetables, free radical scavenging and antioxidant activity. They also have antibacterial, antiviral, anti-inflammatory, antiallergic, anticarcinogenic, and vasodilatory actions [18].

Grape seed extract consists of OPCs in the form of monomeric phenolic compounds such as catechin, epicatechin, and epicatechin-3-O-gallate and free flavanols

monomers [22]. Pine bark extract consists of phenolic compounds generally divided into monomers like catechin, epicatechin, taxifolin, and compacted flavonoids like oligomeric to polymeric proanthocyanidins [23]. Group 4 showed a statistically higher significant mean POBS value than Group 3. The difference in the antioxidant activity might be attributed to their different phenolic compositions, which is in accordance with a study conducted by Subramonian et al. [24]. OPCs (grape seed extract and pine bark extract) reacts with free radicals (e.g., oxygen) generated by the degradation of NaOCl, thereby neutralizing them within the dentin in which they are trapped. Oligomeric proanthocyanidin complex (OPC) contains multiple electron donor sites (hydroxyl sites) that bind to unstable molecules called free radicals by donating its hydrogen atoms [18]. The presence of gallic acid also increases the free radical scavenging activity by esterification of epicatechin [25].

Antioxidants can return the oxidized dentin substrate's redox potential, thereby facilitating the usual setting of the adhesive materials [26]. Furthermore, bioactive compounds derived from OPC (including GSE and PBE) improved the dentin matrix's mechanical properties, impaired biodegradation. It inhibited the action of proteases associated with extracellular matrix breakdown [9]. The interaction between OPC and collagen fibrils involves the formation of complexes that are predominantly stabilized by hydrogen bonding between carbonyl and hydroxyl functional groups of phenols and amide linkages [27].

The treatment of root dentin with OPC could reduce the demineralized dentin matrix's biodegradability and increase the durability between the resin-based sealer and root dentin. OPC rich extracts can also inhibit the activities of MMP and cysteine cathepsins to a greater extent [28]. Besides, the anti-inflammatory and antibacterial properties of OPC are favorable characteristics that could be beneficial in root canal therapies [29].

Limitations

As it was an *in vitro* study, the direct estimation of these results to the clinical application requires further *in vivo* studies.

Conclusion

Within the limitations of this *in vitro* study, it can be concluded that the use of antioxidants as final irrigating solutions can reverse the reduced bond strength of epoxy resin-based sealers to root dentin. The use of 5% pine bark extracts significantly increases epoxy resin-based sealers' bond strength to root dentin compared to no antioxidant therapy.

Assessment of postoperative pain after single-visit root canal treatment using rotary and reciprocating file systems: an *in vivo* study

Reshma Parveen Shaik, Ram Sunil Chukka, Anila Bandlapally, Sayesh Vemuri, Nagesh Bolla, Ram Chowdary Basam, Sravanthi Tammineedi

Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Background: Various instrument kinematics used in single-visit endodontics influence the occurrence of pain after endodontic therapy. This study aimed to evaluate the occurrence of pain after mechanical instrumentation with Hyflex EDM (HEDM) and WaveOne Gold (WOG) during single-visit endodontic therapy.

Methods: Sixty patients diagnosed with asymptomatic irreversible pulpitis and normal apical tissues in mandibular premolar teeth were included in the study for single-visit root canal therapy. The patients were divided into two groups (n = 30) according to the rotary instrument used during root canal preparation (group A [HEDM] and group B [WOG]). Pain was evaluated after endodontic therapy at 8, 24, and 48 h intervals using the visual analog scale (VAS). Data obtained were analyzed using the chi-square test, independent t-test, MannWhitney U test, and Wilcoxon matched-pairs test.

Results: Statistically significant differences were observed between the two groups (P < 0.001) at 8, 24, and 48 h, with WOG exhibiting less pain than HEDM files.

Conclusion: Postoperative pain was lower in the WOG file system than in the HEDM file system after single-visit root canal therapy at 8, 24, and 48 h.

Keywords: Hyflex EDM; Postoperative Pain; Reciprocation; Root Canal Therapy; Rotary Instrumentation; WaveOne Gold.

INTRODUCTION

Pain after endodontic therapy is a routine complication, reported to be 1.4-16% [1-3]. Post-endodontic pain is multifactorial [4]. One underlying cause is debris extrusion during chemomechanical preparation [5-7]. Proper irrigation protocols and aspiration techniques are used to limit instrumentation to the canal's confines, and the extrusion of debris can be minimized using different endodontic files with appropriate kinematics [8,9].

Current mechanical preparation of root canals uses rotary nickel-titanium (NiTi) instruments that employ either of the two kinematics (rotation or reciprocation). Rotary single-file systems, such as Hyflex EDM (HEDM), are produced by a distinctive process called “electric discharging machining.” This technique uses spark erosion, which amplifies the fracture resistance and cutting efficiency [10]. The cross-section of the file varies along the length of the file, with triangular, trapezoidal, and quadratic shapes in the coronal third, middle third, and apical third, respectively [10,11]. WaveOne Gold

(WOG) files are reciprocating files based on M-wire alloy technology with a cross-section of an off-centered parallelogram. This thermal process alters the molecular geometry to increase the cyclic fatigue resistance and improve flexibility [12].

Systematic reviews of postoperative pain when rotary and reciprocating systems were compared after single-visit endodontic therapy have shown different results. Systematic reviews by Hou et al. and Sun et al. stated that rotary instruments result in less postoperative pain, while Martins et al. concluded that reciprocating instruments lead to less pain [13-15]. A systematic review by Spohr et al. stated that no clear conclusion could be drawn regarding the incidence of postoperative pain following the use of rotary and reciprocating instruments, and further well-designed studies are needed in this regard [16]. At this time, the current *in vivo* study was undertaken to assess episodes of pain following endodontic therapy using HEDM (rotary system) and WOG (reciprocating system). The null hypothesis was that there would be no significant difference in the severity of pain following the use of the HEDM and WOG instrumentation systems.

METHODS

This *in vivo* study was approved by the Institutional Ethics Committee (IEC) (14/IEC-SIBAR/CIR/18). Study participants were recruited from the Department of Conservative Dentistry and Endodontics between November 2018 and December 2019. The sample size calculation was performed using G* power 3.1.2. Sixty volunteer patients who met the inclusion criteria were randomized using the sequentially numbered, opaque, sealed envelope method and categorized into two groups of 30 each; group A (HEDM) and group B (WOG) by an endodontist who was blinded to the study protocols. The inclusion criteria were as follows: Patients aged 18-40 years, with single-rooted mandibular premolars diagnosed with asymptomatic irreversible pulpitis with

normal periapical tissue and patients who could understand the use of the pain scale.

The exclusion criteria were as follows: Patients with acute and chronic apical abscess or cellulitis; known allergies to opioids, non-opioids, NSAIDs, analgesics, lidocaine; pregnant or lactating mothers; teeth with complex root canal morphology; teeth with poor prognosis; patients with systemic diseases; unwilling to participate in the study and those receiving premedication with analgesics; and patients with active pain in other than the tooth to be tested.

A thorough treatment protocol was briefed to the participants and informed consent was obtained from all participants. Based on the group assigned to the sealed envelope paper, the respective treatments were performed as described below. The study protocol is shown in Fig. 1.

1. Treatment protocol

The entire clinical procedure was performed by a single surgeon. Local anesthesia was administered with 2% lignocaine (1:80,000 epinephrine) (Astra Zeneca Pharma India Limited, Bangalore, India), followed by reduction in occlusal. After the rubber dam application and access opening, a #10 stainless steel hand K-file was used to establish the glide path. The working length was obtained using the Root ZX apex locator (J. Morita, Kyoto, Japan) and was confirmed using an intraoral periapical radiograph. Mechanical preparation was performed up to size 20 using a stainless steel hand K-file.

Group A (n = 30): The canals were instrumented with HyflexEDM (25/~) (COLTENE/Whaledent AG, Switzerland) NiTi file with a gentle apical stroke and pecking movement with Endomotor X SMART[®] Plus (DentsplyMaillefer, Ballaigues, Switzerland) according to the manufacturer's instructions at 500 rpm and 2.5 Ncm torque.

Group B (n = 30): Mechanical instrumentation with WaveOne Gold primary file (25/0.07) (DENTSPLY Tulsa Dental Specialties, Tulsa, USA) with pecking in and out motion with Endomotor X SMART[®] Plus

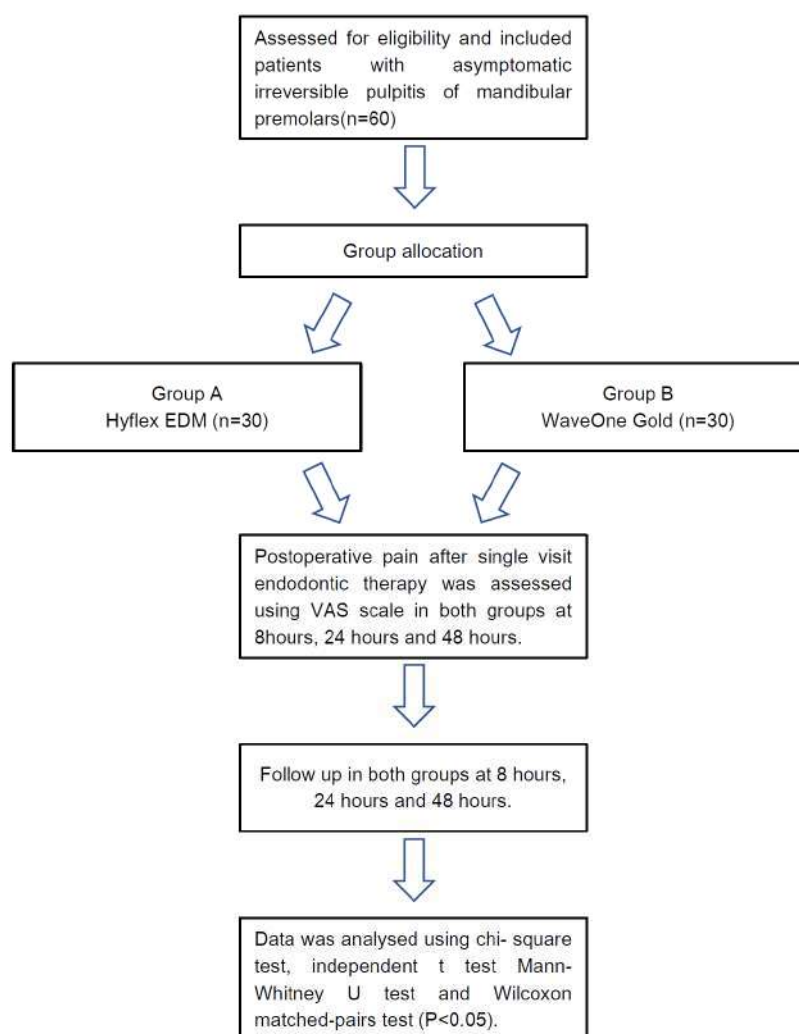

Fig. 1. Flowchart of the study.

(DentsplyMaillefer, Ballaigues, Switzerland) according to the manufacturer's instructions using WOG mode.

In both groups, irrigation was performed intermittently with a 30G side vented needle kept short of working length by 1 mm in the following sequence: 5 ml of 5.25% NaOCl followed by saline (NS, sodium chloride injection, 0.9% W/V) and followed by 5 ml of 17% EDTA solution. With each irrigation flush of NaOCl and EDTA, sonic agitation of the irrigant was performed using an EndoActivator (EA-A0913 022-025 Medium tip Dentsply Sirona, India) for 1 min. Distilled water (10 ml) was used as the final irrigant. Absorbent paper points were used to dry the canals, and the canals were obturated using the corresponding master gutta-percha cone, accessory cones, and a resin sealer (AH Plus, DentsplyMaillefer,

Ballaigues, Switzerland) using the cold lateral compaction technique. A nanohybrid composite resin (Filtek Z250 XT, 3M ESPE, Saint Paul, MN, USA) was used to seal the access openings. The patient's occlusion was evaluated to ensure that the restoration did not interfere with the occlusion. Representative intraoral X-rays of both groups are shown in Figs. 2 and 3.

A visual analog scale (VAS) was used to measure pain after endodontic therapy. Based on this scale, the pain level was numerically documented in the range of 0-100. The following VAS classifications were used: no pain, 0-24; mild pain, 25-49; moderate pain, 50-74; severe pain, 75-100. Pain scoring based on the VAS questionnaire was recorded at 8, 24, and 48 h by telephone inquiry. All patients were prescribed 400 mg of ibuprofen and asked

statistician was blinded to the type of intervention performed. The patients were recalled for definitive restoration after 2 weeks.

2. Statistical analysis

The data were entered into an Excel sheet and analyzed using SPSS version 16.0 (IBM Corporation, India). Data were analyzed using the chi-square test, independent t-test, Mann-Whitney U test, and Wilcoxon signed-rank test. The level of statistical significance was set at 0.05 (P < 0.05).

RESULTS

The sample distribution was revealed to be similar without any statistically significant differences between the two groups regarding sex, age, and tooth type (Tables 1, 2, and 3).

Table 4 shows the comparison of postoperative pain between group A (HEDM) and group B (WOG) at different time intervals (8, 24, and 48 h) using the Mann-Whitney U test. The results showed statistically significant differences between the two groups (P <

0.001) at 8, 24, and 48 h.

Table 5 shows the comparison of different treatment time points with postoperative pain in group A (HEDM) using the Wilcoxon signed-rank test, which showed a gradual reduction in pain intensity with an increase in follow-up time. Group A (HEDM) was shown to have a statistically significant difference between 8 and 24 h ($P = 0.024$) and between 8 and 48 h ($P < 0.001$), but the comparison between 24 and 48 h did not show a significant difference ($P = 0.44$).

Table 6 shows a comparison of different treatment time points with postoperative pain in group B (WOG) using the Wilcoxon signed-rank test, which showed a reduction in postoperative pain with an increase in follow-up time. Group B (WOG) showed a statistically significant difference between 8 and 24 h ($P = 0.001$), 8 and 48 h ($P < 0.001$), and 24 and 48 h ($P = 0.002$).

DISCUSSION

Efficient chemomechanical preparation, three-dimensional filling of root canals, and the degree of postoperative discomfort will influence the success of

endodontic therapy. The subjective nature of pain is difficult to evaluate. Therefore, participants in this study received an adequate description of postoperative pain and VAS scores. This scale is considered a decisive and valid method for assessing pain [2,17].

Most participants interpreted the VAS scale smoothly and estimated their pain intensity appropriately. The two groups were comparable in terms of age, sex, tooth type, and pulpal and periapical status. In this study, a single operator performed endodontic therapy for all participants during a single visit to control the technique and operator-related variables. The only difference was the rotary files used for the mechanical preparation between the two groups.

The file systems used were similar in size to maintain standardization and rule out the effect of varying tapers on postoperative pain [18,19]. Both systems differ in kinematics. Previous studies have reported that postoperative pain is significantly influenced by preoperative pain and periapical status [4]. Therefore, this study admitted teeth with asymptomatic irreversible pulpitis with normal periapical status to evaluate pain after the completion of endodontic therapy.

Single-visit endodontic procedures are preferred to

minimize the effects of related variables. Su et al. reported that the occurrence of pain after endodontic therapy in a single visit was minimal compared with multiple-visit endodontic treatment [20].

In this study, an activator was used in both groups to agitate NaOCl and EDTA for 1 min. EndoActivators can break bacterial biofilms by generating bubbles that expand and collapse, producing miniature shockwaves, thus reducing bacterial stagnation. A study by Vishwakarma et al. reported an improved efficiency in reducing postoperative pain at 8, 24, and 48 h in the EndoActivator group compared to the group with an open-ended needle [21]. Ramamoorthi et al. also found that the EndoActivator group experienced significantly less postoperative pain than the conventional needle protocol at 8, 24, and 48 h [22]. Therefore, activation of irrigants using an EndoActivator can be considered an effective method of reducing postoperative pain.

In the present study, the cold lateral compaction technique was used, as this technique has been shown to cause less postoperative pain than the warm compaction technique [23]. The teeth of both groups were relieved of occlusal contact, as trauma from occlusion would impact the results.

The results of this study revealed significantly less pain in the WOG group than in the HEDM group at 8 h, which was subsequently reduced at 24 h and 48 h. When comparing the VAS between HEDM and WOG in three different time slots, it was found that WOG had higher success than HEDM among participants in terms of the least post-endodontic pain. Therefore, this study showed that WOG was better at minimizing postoperative pain than HEDM.

A systematic review by Pak et al. stated that, during the initial phase, pain after single-visit endodontic treatment was found to be preponderant. According to this review, the mean posttreatment pain severity was greater at 24 h. After 7 days, the severity of the pain gradually reduced [4]. In the present study, the incidence of pain tracked a similar curve, which was greater at 8 h in both groups, followed by a significant reduction in

pain at 24 and 48 h.

A routine prescription of analgesics was not provided in this study, as this would have affected the outcome. Analgesics were advised only on demand. None of the patients in this study required the use of analgesics, as none of them experienced severe pain.

Differences in cleaning and shaping procedures, immune response to extruded root canal debris, irrigants, instrumentation beyond the apex, or foreign body reactions to obturating materials have been reported to cause postoperative pain [19,20]. Therefore, in this study, great care was taken to avoid the influence of these factors.

Superior results were observed for the WOG system compared to the HEDM system. Similarly, the WOG system showed better results than the Protaper system in a study by Saha et al. [24].

The reasons for the lower postoperative pain in the WOG group could be attributed to the following:

1. The WOG has fixed and progressively decreased tapers in D1-D3 and D4-D16, respectively, conserving dentin and maintaining space for more debris to collect and push coronally [25].
2. The off-centric design of WOG with one point of contact with the canal wall results in adequate space for debris collection and removal [26,27].
3. HEDM uses continuous rotational motion with a variable cross-section design, reducing the space for debris clearance [28].

There are various etiological factors for post-endodontic pain, of which the amount of apically extruded debris is the most contributing factor [29,30]. Rotary files have also been shown to cause a greater accumulation of proinflammatory mediators at the periapex than reciprocating files. This could also have contributed to higher pain scores in the HEDM group. The limitations of this study include the sample size and the subjective nature of pain, which are difficult to quantify. The use of hand instruments before the rotary and reciprocating instruments could also be attributed to debris extrusion, resulting in pain. Therefore, more large-scale studies are needed to compare this two

kinematics, focusing on their limitations.

In conclusion, pain after single-visit endodontic treatment was less in patients treated with the WOG system than with the HEDM system. Higher pain scores were observed at 8 h, which gradually decreased in intensity after 24 and 48 h. Since the present *in vivo* study revealed the influence of geometric characteristics of the files on postoperative pain following single-visit endodontic therapy, the findings may help in clinical decision-making in selecting the NiTi instruments and providing a pain-free outcome.

Abstract

Aim. Evaluate the effect of different chromatic filters of the dental operating microscope on the volumetric shrinkage, surface micro-hardness, and depth of cure of bulk-fill composite.

Methods. Bulk fill composite specimens of 4 mm depth, 4 mm width, and 4 mm length were prepared. Five groups were designed based on a light source under which composite samples were condensed. Group 1: dental chair light without filter, Group 2: microscopic light without filter, Group 3: microscopic light with a yellow filter, Group 4: microscopic light with a green filter, Group 5: dental chair light with a red filter. After condensation, the samples were subjected to curing using Bluephase NM curing light. The parameters like volumetric shrinkage, surface hardness, and depth of cure were measured for all the samples. The results were subjected to statistical analysis using one-way ANOVA, followed by post-hoc Tukey tests.

Results. Group-2 showed the highest mean volumetric shrinkage (14.514%), surface micro-hardness (58.065 kg/m²), depth of cure (0.831%), whereas group-5 showed the least volumetric shrinkage (7.386%), surface micro-hardness (46.536 kg/m²), and depth of cure (0.789%). Working time was 40 seconds for group-2, whereas the remaining groups were allowed to complete 1-minute condensation. A statistically significant difference was shown between groups 1 and 5 (p=0.050), 2 and 5 (p=0.007) for volumetric shrinkage. Regarding surface micro-hardness, a statistically significant difference was observed between all the groups (p=0.001) except group-3, group-4 (p=0.100). There was no statistically significant difference between all the groups except group 2 and 5 for depth of cure (p=0.016).

Conclusion. Microscope light without filter showed the highest surface hardness and depth of cure. However, the highest volumetric shrinkage and lesser working time were also observed, which are undesirable. Use of filters during composite manipulation showed less detrimental effects on depth of cure, volumetric shrinkage and working time. Overall, composite condensed under filters showed acceptable properties.

Keywords: bulk fill composite, intensity, microscopic light filters, surface hardness, volumetric shrinkage

Introduction

Today's dentistry is more focused on the attention to detail. Micro restorative dentistry is an emerging trend in this perspective. Many anterior as well as posterior esthetic restorations, warrant the use of magnification [1]. Dental Operating microscopes (DOM) are provided with different chromatic filters for versatile applications. Literature suggests that the mechanical properties of composite resin can be influenced by different light source [2,3]. There is a linear relationship between light intensity and polymerization shrinkage, i.e., the higher the intensity of light, the higher the polymerization shrinkage [4-6]. Also, the degree of conversion (DC) of composite resin can determine the mechanical properties, chemical stability, and longevity of a restoration. Efficient polymerization is important for obtaining the optimal physical properties of the material and achieving improved clinical performance of resin composite restorations [7]. The hardness of the light-cured resin composites depends on several factors: the composition of the organic matrix, the type and amount of filler particles, and the degree of polymerization. An examination of the resin composite micro-hardness was used to evaluate the rate of polymerization [8,9].

While the relative degree of cure of the external surface of a restoration can usually be evaluated with simple techniques, the cure of the inner layers of resin is not similarly accessible to evaluation. It was recognized that, unlike chemically activated resins, an adequate cure of the entire visible light activated restoration cannot be assumed, based on external surface properties [10]. It has been shown that inadequate polymerization would result in a reduction in physical properties [11]. A number of different techniques have been employed to measure the properties of the polymerized resin composite which include scraping away the unset material and measuring the remaining specimen, measuring top and bottom hardness and measuring top and bottom degree of conversion of double bonds in the polymer [12,13]. Micro-hardness (MH) is an indirect measure of a material's depth of cure (DOC). It provides valuable information on the DOC when measured on the top and bottom surfaces of a specimen. The depth at which a composite resin achieves 80% of its surface hardness is generally considered the maximum depth at which the composite should be used [14,15].

Despite advances in the composite resin itself, compensation for volumetric shrinkage (VS), post-cure density, and surface hardness are the considerable challenges that play a significant role in durability. It is claimed that bulk-fill composites can obtain an optimal degree of conversion even at the bottom of the cavities [16,17]. But little is known about the effect of microscope filters on the properties of the bulk-fill composite. The study aims to evaluate the effect of microscopic filters on the surface hardness, depth of cure, volumetric shrinkage of the bulk-fill composite.

Methods

Forty molds of 4 mm width, 4 mm length, 4 mm depth were used to condense the Tetric-N-Ceram bulk fill (IvoclarVivadent, shade A2) composite. Manipulation of composite specimens was carried under respective microscopic filters (Magna, Labomed) in a dark environment to prevent the deleterious effects caused by the daylight and then cured with Bluephase NM curing light (Ivoclar, Vivadent).

Based on the type of light source under which composite specimens were prepared, five groups were designed.

Group 1: composite condensed under dental chair light.

Group 2: composite condensed under microscopic light without the filter (Figure 1).

Group 3: composite condensed under microscopic light with a yellow filter (Figure 2).

Group 4: composite condensed under microscopic light with green filter (Figure 3).

Group 5: composite condensed under dental chair light with a red filter (Figure 4).

Figure 3. Composite condensed under microscopic light with green filter.

Figure 4. Composite condensed under dental chair light with a red filter.

Each group contains a total of 8 specimens. The distance between the illuminant and sample was maintained at 30 cm and was kept constant. After condensation for 1 minute with a plastic filling instrument, we covered the composite specimen surface with a mylar strip and placed the curing light upon it. The size of the illuminated area was 8cm. The irradiance on the surface of the specimen with microscopic light was 1 lakh lux, and with the placement of filters, it was 75,000 lux. Under the chair light, irradiance on the sample's surface was 30,000 lux, and with a red filter, it reduced up to 20%. Bluephase NM (Ivoclar) was used to cure the samples with an intensity of 800 mW/cm² and a wavelength range of 430-490 nm for 15 sec. Later, each specimen was removed from the mold, stored in artificial saliva for seven days, and placed in an amber bottle. Amber bottles were stored in a humidifier until testing. Initially, we calculated the volumetric shrinkage using a micrometer. Later all the samples were

tested for top and bottom hardness using Vickers micro-hardness tester and calculated the depth of cure.

Measurement of volumetric shrinkage

Three sides of the post-cured composite specimen (length, width, height) were measured using a micrometer. All three values multiplied to obtain the volume of the post-cured composite specimen. The difference in the mold and post cured composite specimen volume was calculated, and that value was taken as volumetric shrinkage.

Measurement of micro-hardness

The top and bottom surface hardness of each 4-mm increment specimen were measured using the Vickers micro-hardness tester (Daksh quality system, India). The measuring indenter, the Vickers pyramid, was pressed to the composite sample using a load of 100 grams for 20 sec. The surface Vickers hardness was measured at three points of each specimen to minimize measurement errors within a sample.

The average of the three micro-hardness values was taken to obtain a single value of Vickers micro-hardness.

Equation 1: Vickers hardness of the material (VHN) = (1.8544P)/D²

In which VHN represents Vickers's hardness of the material (kg/m²), P is the predetermined load applied on the sample (kg) and D is the average diagonal distance (mm) of the square resulting from the indentation of the pyramid tip of Vickers hardness tester.

Depth of cure measurement

After determining the top and bottom micro-hardness, the depth of cure of each sample was calculated according to Equation 2.

Equation 2: Depth of cure = bottom micro-hardness/top micro-hardness

Working time was measured simultaneously using a stopwatch while condensing the composite into the molds until resistance to condensation was observed.

Statistical analysis

The collected data were subjected to descriptive analysis and followed by Mann-Whitney u test to measure the outcome variables in different groups. One way ANOVA was performed to know the mean comparison within and between the groups of outcome variables followed by Tukey post hoc test for multiple group comparisons. The statistical significance level was set as p<0.05. The analysis was performed using SPSS software version 20.0 IBM (NY, USA).

Results

Group-2 showed the highest mean volumetric shrinkage (14.514%), whereas group-5 showed the lowest (7.386%) among all the groups (Table I). A statistically significant difference is demonstrated between group 1 and 5 (p=0.050), 2 and 5 (p=0.007) (Table II).

Table I. Comparison of mean values of volumetric shrinkage, surface hardness, depth of cure of all the groups.

Group	Mean Volumetric Shrinkage (%)	Mean Surface Micro-Hardness (kg/m ²)	Mean Depth of Cure (%) (Bottom/Top Surface Hardness)
Group-1	12.868	51.994	0.811
Group-2	14.514	58.065	0.831
Group-3	12.055	50.966	0.800
Group-4	10.842	50.434	0.803
Group-5	7.386	46.536	0.789

For group-2 samples, the average working time recorded was 40 sec, whereas the remaining groups showed 1 minute working time.

Discussion

Bulk-filling techniques are popularized due to the introduction of materials with improved curing, controlled polymerization contraction stresses, and reduced cuspal deflection [18-22]. By this approach, the number of increments required to fill a cavity is decreased compared to traditional incremental techniques. In contrast to the 2-mm incremental technique for conventional composites, manufacturers recommend 4-5-mm increments of the bulk-fill resin composites. The bulk-fill method undoubtedly simplifies the restorative procedure and saves clinical time in cases of deep, wide cavities.

The incident light influences the properties of these bulk-fill composites. The use of a microscope, combined with co-axial illumination (MLMCI), improves the dentist's ability to prepare, bond, restore, and adjust composite restorations, compared to use unaided vision and non-co-axial, shadow forming overhead lighting [23,24]. A co-axial light axis is coincident with the visual axis of the dentist's eyes, resulting in shadow-free illumination [25,26]. DOM are provided with different types of filters and are used for observation and photomicroscopy. Each microscope filter placed in the light path serves a different purpose and is placed either over the illuminator or in a filter slot that lies in the light path. The dental operating microscope used in

this study has inbuilt yellow and green filters. We added a red filter to the dental chair to compare the effects of the different lights (dental chair light and microscopic light) with and without filters.

The higher the light intensity, the higher the degree of conversion, and higher the polymerization shrinkage [27]. High polymerization shrinkage in group 2 could be because of the high intensity of DOM light without filter while condensing, followed by curing light intensity. Similarly, low polymerization shrinkage in group 5 could be because of the low intensity of dental chair light with a filter. Groups without filters showed higher volumetric shrinkage values when compared to groups with filters.

Micro-hardness is an essential parameter for the physical and mechanical behavior of composite resin restorations. The hardness of the light-cured resin composites depends on several factors: the composition of the organic matrix, the type and amount of filler particles, and the degree of polymerization and distance between the composite and tip of curing light [28]. Since all the factors except the degree of polymerization are made constant, and it could be the only factor that changed properties. The degree of polymerization, in turn, depends upon the light source and its intensity. Greater SH in Group-2 is because of the higher intensity of the light source, which increased the DC.

Similarly, Group-5 specimens were subjected to a lower intensity of light, giving lower SH values. Similar results were shown by Kassim et al., where the DOC and SH increased with an increase in light intensity up to 1500 mW/cm² [29]. There is no statistically significant difference between groups 3 and 4, which could be because of manipulation under similar conditions except for the change in filters. A significant difference was observed for group 2 (without filter) with group 3 and group 4 (both with filters); this might be because of a 35% decrease in the microscopic light intensity. According to the manufacturer's specifications, the microscopic light intensity is nearly 1 lakh lux, which decreased to 75,000 lux approximately with the filters.

SH is not an adequate indicator of complete material polymerization. The hardness of the bottom surface should be close to the hardness of the top surface. A value of over 0.80 in the bottom to top surface micro-hardness indicates adequate DOC. The DOC is the depth up to which the light can cure the material. The presence of unreacted monomer within the resin-based composite (RBC) bulk may also attenuate the irradiating light, preventing the formation of free radicals and thereby reducing the DOC. All the groups showed a considerable DOC (>0.8) except group-5 (0.78), which is because of lower hardness values in the case of Group 5. The chemical composition of the filler and matrix can have significant effects on the degree of conversion of RBCs. Tetric N Ceram bulk-fill composite has prepolymerized fillers (PPF) containing barium glass

and silica minerals. New types of photo-initiators such as Ivocerin and Benzoyl Germanium are used in the composition of PPF of bulk-fill RBCs instead of the standard type camphor quinone (CQ) [30]. The higher capability of these materials in creating free radicals per molecule unit can improve the light sensitivity of RBCs [31]. These changes have a positive effect on the light absorbance ability and DC of RBCs.

All the parameters were lower for group 5 when compared with group 1. Groups 1 and 5 showed significant differences for SH and VH. The difference could be because of the reduction of the intensity of the chair light after placing the filter. The working time is less in Group 2 because of the high intensity of light, causing the rapid formation of a highly cross linked polymeric network in surface layers of composite resin. The remaining groups showed an adequate working time.

Conclusion

Microscope light without filter showed the highest surface hardness and depth of cure. However the highest volumetric shrinkage and lesser working time were also observed, which are undesirable. Use of filters during composite manipulation showed less detrimental effects on depth of cure, volumetric shrinkage and working time. Overall, composite condensed under filters showed acceptable properties.

Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Background: Tooth whitening procedures such as bleaching and microabrasion alters the enamel surface and thus reduce the composites' bond strength. Hence, various surface treatments were introduced to overcome this problem.

Aim: To assess the effect of nonthermal atmospheric plasma (NTAP), grape seed extract (GSE) and bromelain on the shear bond strength (SBS) of the composite after bleaching and microabrasion.

Materials and Methods: Eighty extracted maxillary anterior teeth were distributed into two groups. Group 1: bleaching and Group 2: Microabrasion and further subdivided into four subgroups ($n = 10$) based on the form of surface treatment employed. Group A: no surface treatment, Group B: bromelain, Group C: GSE, Group D: NTAP. Composite resin was bonded to the labial surface and placed in artificial saliva for 24 h. SBS testing was done for all the samples.

Statistical Analysis: Analysis was performed using two-way analysis of variance and *post hoc* Tukey's test with $P < 0.05$ considered statistically significant.

Results: Group 1D revealed the highest bond strength (35.4 Mpa) and Group 1A showed the least bond strength values (15.7 Mpa). Among the bleaching groups, significant difference was observed between all the subgroups except Group 1A and 1B ($P = 0.972$). In microabrasion group, significant difference was observed between Group 2A and 2D ($P = 0.0001$), Group 2B and 2D ($P = 0.0010$), and Group 2C and 2D ($P = 0.0001$).

Conclusions: Following bleaching, NTAP application and GSE significantly improved the SBS of composite resin. Application of NTAP to microabraded surfaces increased the bond strength of composite resin.

Keywords: Bleaching; bromelain; grape seed extract; microabrasion; nonthermal atmospheric plasma

INTRODUCTION

Intrinsic enamel defects, such as opacities and brown pigmentations can adversely affect the color, translucency of enamel. Depending on the severity of the

defects, various treatment modalities such as bleaching, microabrasion, veneers, and crowns are performed.^[1] However, bleaching remains the mainstay of treatment for these intrinsic stains. The bleaching agent slowly interacts with stains located within the superficial layers of the tooth and thus lightens the tooth surface.^[2] Hydrogen peroxide (H_2O_2) has side effects such as tooth sensitivity, external cervical resorption, and reduction of composites' bond strength when bonded immediately

to the bleached surface. The standard method to overcome this problem is to delay the bonding for up to 4 weeks following bleaching.^[3] A variety of methods have been proposed to overcome this problem, which includes superficial tooth reduction, alcohol application before bonding, using acetone-based adhesives, and antioxidants such as alpha-tocopherol and sodium ascorbate.^[4]

Grape seed extract (GSE) is a natural antioxidant that contains 98% of oligomeric proanthocyanidin complexes (OPCs). OPCs contain electron donor sites, i.e., hydroxyl sites, which binds to the free radicals. They neutralize the free radicals trapped in the enamel following the degradation of H₂O₂. There is a need to compare the effect of applying these antioxidants to bleached surfaces with other surface treatment procedures.^[4]

Espinosa *et al.* stated that Enamel deproteinization before etching increases the retentive surface of the enamel to 94.47%.^[5] Deproteinizing enzymes like bromelain remove the unsupported collagen, thereby increasing the dentin permeability and enhancing the diffusion of monomers. Bromelain was reported to decrease nanoleakage following the removal of collagen.^[6] However, there are no studies evaluating the efficacy of bromelain following bleaching on the shear bond strength (SBS) of composite to the tooth surface.

In recent times, plasma has gained considerable importance in the medical field. Plasma is a partially ionized gas and known as the fourth state of matter. Nonthermal atmospheric plasma (NTAP) is a low-temperature artificially generated gas, which does not use a vacuum system.^[7] Various studies have reported the increase in composite resin's bond strength to the tooth surface using proteolytic enzymes, antioxidants, and NTAP. However, limited literature is available regarding the effect of bromelain, and NTAP on the bond strength of composites immediately following the tooth whitening systems.

Microabrasion is a simultaneous procedure of abrasion and erosion, reducing the superficial enamel resulting in a compact, prism-free layer. It comprises dense mineralized tissue in an organic matrix, which is replaced by a densely compacted prismless layer. Thus, by altering the enamel surface, it reduces the composites' bond strength.^[8] Opinya *et al.* observed that removal of the compact mineralized layer can improve the composites' bond strength.^[9] Hence, there is a need to study the effect of various surface treatments on microabraded surfaces. The present work aimed to assess the impact of bromelain, GSE, and NTAP on the SBS of composite resin following bleaching and microabrasion.

MATERIALS AND METHODS

After obtaining ethical clearance from the institutional ethics committee (Pr. 139/IEC/SIBAR/2018), eighty human maxillary anterior teeth ($n = 80$), extracted for various reasons, were selected for the study. The samples were thoroughly cleaned and were mounted in plastic molds with self-cure acrylic resin until the cemento-enamel junction. The facial tooth surfaces were cleaned with pumice slurry. The samples were allocated into two groups based on the teeth whitening systems ($n = 40$ each).

Treating with tooth whitening systems

Group 1 ($n = 40$): the labial tooth surfaces were dried. Pola Office syringe (SDI limited, Australia) is taken, the plunger is pulled back to release pressure and extrude the contents into the pot supplied by the manufacturer. Immediately mixing is done using an applicator tip until a homogeneous mixture is obtained. Generous amount of this gel is applied on the labial surface for 8 min. The bleaching gel is then rinsed and blot dried.

In Group 2 ($n = 40$): a fine grit diamond bur with water coolant is used to slightly remove the labial surface superficially to initiate micro reduction. A plastic mac tip supplied by the manufacturer was attached to the Opalustre (Ultradent, USA) syringe. 1 mm thick layer is applied uniformly on the tooth's labial surface. A micromotor handpiece with Opal prophyl cups was used at RPM of 400, along on the enamel surface for 120 s. Following this, the teeth were rinsed with distilled water.

The groups were subdivided into four subgroups: A, B, C, and D, respectively, based on the type of surface treatment performed.

Subgroup A ($n = 10$): No surface treatment is done (control group).

Subgroup B ($n = 10$): 5% bromelain solution for 10 min and then rinsed with distilled water.

Subgroup C ($n = 10$): 5% GSE solution for 10 min and then rinsed with distilled water.

Subgroup D ($n = 10$): NTAP exposed for 15 s.

Preparation of solutions

1. Proteolytic enzyme– 5% bromelain solution-5 gm of bromelain (Meteoric Exim Pvt. Ltd., India) dissolved in 100 ml of distilled water
2. Antioxidant– 5% GSE solution-5 g of GSE (All pure organics, India) dissolved in 100 ml of distilled water.

Nonthermal atmospheric plasma application

To generate the plasma jet, compressed He gas with a pulsing head of 2 GHz at 3.25 standard liters was utilized.

Banu, *et al.*: Surface treatments on bleached and microabraded surfaces

The NTAP was applied at a pressure <2 Pascal's and a power of 2 Watt [Figure 1]. The application was carried out in an isolated closed chamber at a distance of 5–6 mm from the tooth surface for 15 s for each sample with an alternating cycle of activation and resting phase of 5 s each. The temperature on the tooth surface was also examined using a thermocouple which ranged from 27 to 29.4°C, that is endured by pulpal tissues.

Placement of composite restoration

For all the groups, the composite placement was carried out immediately after surface treatment. Self-etch adhesive (Solare Universal bond, GC, India) was applied to the labial surfaces of the tooth. A cylindrical plastic matrix of 3 mm diameter and 3 mm height was prepared. The matrix was placed on the labial surface and the composite resin (Spectrum, Dentsply, USA) was condensed incrementally. It was then photopolymerized in all directions using light-emitting diode light-curing unit (Orikam Eighteenth Curing Pen, India) for 60 s. The matrix was removed carefully following polymerization. The samples were then placed in artificial saliva for 24 h at 37°C. SBS testing was performed for all the samples using Universal Testing Machine (UTM) (Instron, Model 8801). Each sample was secured in UTM in such a way that the leading edge of the plunger is targeted at the interface between composite and labial surface at 1 mm/min speed. The force needed to dislodge the composite material was noted. The SBS was calculated using N/mm² (peak load value/composite base area).

Statistical analysis

The data obtained were analyzed using version 20.0. SPSS software (Statistical Package for the Social science, IBM Corp. Ltd., Armonk, NY, USA). All the groups were analyzed for overall significance values using two-way analysis of variance test, whereas, comparison within the group and intergroup comparisons were made utilizing *post hoc*

Figure 1: Application of nonthermal atmospheric plasma

Tukey's tests with $P < 0.05$ was considered as statistically significant.

RESULTS

The results showed that Group 1D had higher bond strength (35.4 Mpa) out of all the groups, and Group 1A with least bond strength values (15.7 Mpa). In the bleaching groups, significant differences were observed between all the subgroups except Group 1A and 1B ($P = 0.972$) [Table 1]. In microabrasion group, significant differences were observed between Group 2A and 2D ($P = 0.0001$), Group 2B and 2D ($P = 0.0010$), and Group 2C and 2D ($P = 0.0001$) [Table 2].

DISCUSSION

The bleaching procedure might exhibit definite antagonistic effects on the enamel. These include a decrease in the surface microhardness, morphological as well as compositional changes.^[10] These changes may affect the bonding of restorations to enamel when applied immediately postbleaching. According to the literature, tooth bleaching may reduce composites' bond strength applied to bleached enamel. Smith *et al.* stated significant surface structural changes in bleached enamel. According to them, fundamental changes may be the cause of the reduction in bonding strength.^[11] Several reports have been reported regarding the association between bleaching agents and changes in the chemical or morphological structure of enamel.^[12] These modifications include loss of calcium and regular prism margins, change

in the ratio of the organic and inorganic constituents of the tooth.

In the present study, bleaching followed by immediate bonding of composite resin with no surface treatments showed the least bond strength. This finding is similar to the previous investigation by Nimet *et al.* who reported a drop in the mean bond strength value of composite by half due to the application of 35% H₂O₂.^[13] Physical alterations in the tooth structure after bleaching were the probable reason for the decrease in enamel bond strength. Similar decrease in bond strength was reported by Cinthia *et al.*, Khamverdi *et al.*^[14,15] this decrease in bond strength may be due to scanty, small, and poorly distinct resin tags bonded to bleached teeth. The eminence of these resin tags, their frequency, and their depth of penetration effect the bond strength of composite to the enamel, as mentioned in the research done by Titley *et al.*^[11] Similar short, sparse, structurally incomplete, or complete absent resin tags in bleached enamel was reported by Dishman *et al.*^[16]

Torneck *et al.* showed a substantial decrease in composite resin's adhesive bond strength following exposure of enamel to H₂O₂.^[17] The residual peroxides on the enamel surface are responsible for the bond failure that happened at the resin-enamel interface. Rinsing leads to the residual H₂O₂ washout only on the superficial enamel (0.5–5 nm).^[18] However, the residual free radicals trapped deep inside the enamel could have attributed to the compromised bond strength. Reversal of the reduced bond strength can be achieved in two ways. The first one is the time-dependent delay of composite placement, while the latter is by surface treatments performed on the bleached enamel using alcohol, acetone-based adhesives, and antioxidants.

In the current study, bromelain was used as an experimental surface treatment agent. Bromelain is commonly used in medical supplements. The pH of the bromelain ranges from 3 to 6.5. At this pH, the bromelain components are stable, and it disrupts adhered proteins causing stains. According to Aarti *et al.* there is a significant increase in microleakage after bleaching with 35% H₂O₂ and effectively reduced when the bleached teeth were treated with bromelain.^[19] However, their methodology involved class V cavity preparation on the cervical third of the teeth. Better results for bromelain group in their study could be due to dentin involvement while cavity preparation, thereby exposing the collagen substrate for the bromelain to act. In the present study, bromelain showed no statistical significance when compared to the control group. This could be because the bromelain acts on the protein content, which is less in enamel.

To overcome the failure of immediate bonding to bleached enamel, Vidya *et al.* studied the effectiveness of antioxidants in the reversal of decreased adhesion to the bleached

surface.^[4] Nair *et al.* and Rose *et al.* studied that antioxidant agents have the potential to eliminate free radicals, thereby minimizing the interference with the polymerization of adhesives, which in turn can improve the bond strength of composites to bleached surface.^[20]

GSE is a natural antioxidant that contains 98% of OPCs.^[20] When compared to control, GSE significantly improved the bond strength. OPCs contain electron donor sites, i.e., hydroxyl sites, which binds to the free radicals. They neutralize the free radicals trapped in the enamel following the degradation of H₂O₂. This potential of OPCs is said to be 50 times superior than other antioxidants.^[4,6]

In the microabrasion group, control samples showed the least bond strength. Microabrasion increases the roughness of the enamel surface and is also related to the reduction in the enamel microhardness. The abrasion of enamel rods causes the formation of by-products which get compacted on the micro abraded surface. This results in a surface which is impervious to etching.^[8] Group 2B showed no improvement in mean SBS values, which could be because the bromelain acts on the protein content, which is less in enamel. As there is no free radical production, even the application of antioxidants did not show improved bond strength in Group 2C.

Plasma is the fourth state of matter, an extremely reactive material comprises charged particles, and a strong electric field. Plasma treatment increased hydrophilicity of the dental materials on the dentin surface, thereby reducing the interface defects/voids and improve the interfacial quality.^[21] In the current study, NTAP application to both bleached and microabraded surfaces, i.e., Groups 1D, 2D significantly improved the bond strength. This is in accordance with several studies which have proven NTAP to increase bond strength at the interface of tooth and composite by 60%.^[22] This bonding at the interface helps in improving durability, longevity, and performance of the composite resin.^[23]

Plasma application increases the wettability, hydrophilicity of the substrate and modifies its chemical structure by provisionally exposing and partially dispersing the functional groups. This results in improved infiltration of the bonding agent into the enamel and enhances the adhesive bond strength producing bonds that depend on surface chemistry rather than surface porosity, which is in accordance with Cho *et al.*^[24] Even though the resin tags do not significantly contribute to the bond strength in the case of self-etch adhesives, the enhanced resin tag formation by NTAP in the present study could have contributed to the rise in initial bond strength.^[7,21]

NTAP causes molecular alterations such as reducing the molecules containing nitrogen and carbon and exposing the

Banu, *et al.*: Surface treatments on bleached and microabraded surfaces

hydroxyapatite crystals, which is considered a significant improvement in the wettability of enamel. Short exposure periods of enamel surfaces to NTAP for only 30 s lead to the formation of super hydrophilic surfaces.^[25] There appears to be a need for further clinical studies to compare and gather more details of plasma effects on the organic components of enamel, analyzing the different periods of plasma application and its implications on adhesive properties to the bleached and micro abraded enamel to support the present hypothesis.

Limitations of the study

1. In the present study, even though plasma has shown better results of increased bond strength, the use of the same in the clinical scenario is practically difficult
2. The results have to be confirmed with large-scale and *in vivo* studies.

CONCLUSIONS

- Composite resin application immediately following bleaching and microabrasion showed decreased mean SBS values
- Following bleaching, NTAP, and GSE application significantly improved the SBS of composite resin
- Following microabrasion, NTAP significantly increased the SBS of composite resin.

ABSTRACT

Aim: The aim of this study was to evaluate the sealing ability of mineral trioxide aggregate (MTA), Biodentine with and without Bioactive glass (BG) as furcation repair materials by ultraviolet (UV) spectrophotometric analysis.

Materials and Methods: Forty extracted human maxillary molars ($n = 40$) were selected and decoronated 3 mm above the cemento-enamel junction and 3 mm below it and a defect in furcation was created. The samples were then divided into 4 groups of 10 ($n = 10$) each, Group I: MTA, Group II: Biodentine, Group III: BG + Biodentine and Group IV: BG + MTA and the defect was treated with respective furcation repair material. All the samples were then immersed in 2% methylene blue solution for 24 h and later stored in 65% nitric acid solution. The solution obtained was subjected to centrifuge at 3500 rpm for 5 min. From this solution, 100 μ l of the supernatant was collected, analyzed in UV spectrophotometer at 550 nm with nitric acid as the blank and readings were recorded as absorbance units.

Results: All four groups exhibited a significant difference in dye absorbance values ($P < 0.01$). Group I, i.e., MTA showed the least dye absorbance values when compared with the other three groups. Data were analyzed using one-way analysis of variance and *post hoc* Tukey tests. The level of statistical significance was set at $P < 0.05$.

Conclusion: Within the limitations of the study, it can be concluded that MTA had superior sealing ability than Biodentine, whereas BG + Biodentine showed better sealing ability when compared with BG + MTA.

Keywords: Calcium silicate cement, furcation, mineral trioxide aggregate

INTRODUCTION

The physiological dentition serves as a defense against pathologies. On the other version, it also harbors diverse microbiota, which leads to the pathologies and failure of treatment progress. Endodontic mishaps occur because of iatrogenic causes. However, repair of these mishaps plays a pivotal role in the procedure's success. Furcation perforation is one such mishap.^[1]

Antecedently, amalgam, gutta-percha, calcium hydroxide, calcium sulfate-based materials have been used as furcation repair materials. These materials exhibited some potential risk factors leading to the destruction of the periodontium. Some of these materials are no longer preferred as a furcation

repair material. Nowadays, Glass Ionomer Cement, mineral trioxide aggregate (MTA), Biodentine, Bioactive Glass (BG), Demineralized Freeze-Dried Bone, Tricalcium Phosphate, and Dentine Chips are the most commonly used perforation repair materials.^[1]

The advancements in the furcation repair material were majorly to overcome the sealing ability of the material with the tooth structure, biocompatible to promote the healing of the underlying periodontal tissue, and control of the repair material to avoid its extrusion into the periodontal tissue, antibacterial property. Furcation repair material should induce healing, bone formation, be radiopaque, induce mineralization, cementogenesis, comfortable in manipulation and placement.^[2]

MTA is one of the materials of choice to repair the furcation perforation because of its superior quality of marginal adaption, sealing ability, antibacterial effects, biocompatibility, and bioactivity, which may induce the regeneration of periodontal tissue. MTA's major disadvantage is its delayed setting time, which compromises initial setting time when in contact with oral fluids and diminishes the adaptation of the MTA to tooth structure.^[3] Biodentine is a calcium silicate-based material with a polycarboxylate-based hydro-soluble polymer system described as a water-reducing agent, reducing the mix's overall water content, along with calcium chloride as the setting accelerator.^[4]

BG is a potentially new repair material introduced in dentistry as a root-end filling material. BG is a type of bioactive ceramic consisting of SiO₂, CaO₅, Na₂O, P₂O₅. It is well suited as a repair material for a variety of endodontic treatments. BG has adequate strength and load-bearing capacity, good handling, and working properties.^[5,6] It has a faster setting time of around 15 min,^[7,8] tolerates moist environment very well, good marginal adaptation, low cytotoxicity comparable to MTA.^[8]

In the present *in vitro* study, BG is attempted by modifying the polymer/powder part of bone cement with MTA or Biodentine. All the favorable properties of BG are retained and the potential disadvantages faced with MTA or Biodentine are overcome. The purpose of the current study was to evaluate the sealing ability of MTA, Biodentine, BG + Biodentine, BG + MTA as furcation repair materials using the dye extraction method.

MATERIALS AND METHODS

Forty freshly extracted human maxillary molars ($n = 40$) with nonfused and well-developed roots were collected for the

study and stored in 0.2% thymol solution until use. The sample size was calculated using G*power 3.1.9.4 software (Heinrich Heine University, Düsseldorf, North Rhine-Westphalia) at an effective size of 1.39, error probability of 5% and 95% power, a minimum sample of 16 with 4 samples in each of the four study groups is required. The teeth were made free from any calculus, soft tissue, and debris with an ultrasonic scaler. Each tooth was then decoronated 3 mm above the cemento-enamel junction (CEJ) and 3 mm below the furcation. The sectioned surface and root canal were covered with sticky wax on the external root surface, in the orifice and then two layers of varnish were applied over them, a black marker pen was used to mark the location of the defect. Artificial perforation of 1 mm in diameter was created from the external surface of the tooth with the number a #2 round carbide bur (Mani Inc., Japan) mounted on a high-speed handpiece with air-water coolant. For standardization purposes, the perforation was created in the floor of the pulp chamber from the external tooth surface to ensure that each perforation is to be centered between the roots with standard dimensions, without any access deviations for all samples. The chamber and perforation were flushed with water and dried. This methodology was similar to the one that was followed by Balachandran and Gurucharan.^[9]

The samples ($n = 40$) were then divided into four groups ($n = 10$) based on the furcation perforation repair material used.

Group I ($n = 10$): MTA: Ten molars in which perforations were repaired with Pro Root MTA (Dentsply Malleifer, USA)

Group II ($n = 10$): Biodentine: Ten molars in which perforations were repaired with Biodentine (Septodont, Saint Maur des Fosses, France)

Group III ($n = 10$): BG + Biodentine = Bioactive bone cement: Ten molars in which perforations were repaired with Bioactive bone cement.

Group IV ($n = 10$): BG + MTA = Bioactive bone cement: Ten molars in which perforations were repaired with Bioactive bone cement.

All the materials were manipulated according to the manufacturer's recommendations and placed incrementally with the help of a plastic filling instrument. The material condensation was done with the cylindrical end of the plastic filling instrument until the repair material was extruded out of the tooth surface and extruded repair material was removed with the flat end of the plastic filling instrument.

Preparation of bioactive bone cement

To prepare the bioactive bone cement powder and liquid of both the MTA and Biodentine were modified. The ratio for MTA/Biodentine: BG was 60:40 for powder, and for liquid, it is 1 ml of monomer liquid: 1 drop of saline coupling agent. The mixing of the cement was carried out in Amalgamator (Ultram 2, SDI, Australia). The modified powder and liquid were mixed together in the ratio of 2:1. Each sample was then repaired with the respective material in each group and stored for 24 h.

Evaluation of microleakage method

All the samples in each group were placed in separate Petri dishes containing 2% methylene blue. The teeth were immersed in dye up to the CEJ for retrograde dye challenge and dye was added to the access chamber of each tooth so that it was filled for orthograde dye challenge. All samples were stored similarly for 48 h.

All the samples were rinsed under tap water for 30 min and varnish was removed with a polishing disc. Each tooth was stored in a vial containing 5 ml of concentrated (65 wt %) nitric acid for 3 days. The solution thus obtained was subjected to centrifuge at 3500 rpm for 5 min. From this solution, 100 µl of the supernatant was collected, then analyzed in an ultraviolet spectrophotometer at 550 nm with nitric acid as the blank, and readings were recorded as absorbance units. The results thus obtained were subjected to statistical analysis. One-way ANOVA, followed by *post hoc*-Tukey tests were done using the statistical package SPSS (Statistical Package for Social Science, version 21, IBM Corp. Released 2012. IBM SPSS Statistics for Windows, Version 21.0. Armonk, NY: IBM Corp).

RESULTS

Mean spectrophotometric dye absorbance values of four different experimental groups.

Meanspectrophotometric dye absorbance values of four different experimental groups have been presented in Table 1. The least absorbance value was obtained for MTA (Group I - 0.484), followed by Biodentine (Group II- 0.555). The highestabsorbance values were obtained for Bioactive glass + MTA (Group IV- 0.890), when compared with Bioactive glass + Biodentine (Group III- 0.706). The meandye absorbance values were comparatively higher in the Bioactive bone cement groups i.e., Group III, Group IV when compared to the MTA (Group I) and Biodentine (Group II) alone. There was no significant difference between Group I and Group II. Group III showed absorbance values slightly higher than Group I and Group II.

DISCUSSION

Endodontic mishaps consist of various procedural accidents, perforation located in any tooth region is one such accident that may be accessed cavity preparation related. Irrespective of their situation, these perforations may serve as a connection between the external and internal tooth surface, leading to a decrease in the endodontic treatment's successful outcome. Repairing these perforations immediately with biocompatible material will increase the chances of the success of the endodontic treatment.

In this *in vitro* study, the sealing ability was assessed by the dye extraction method, which according to Camps and Pashley, gives similar results to the fluid filtration technique; both are based on quantitative measurement of liquid passage within the interfaces.^[10] In the dye extraction method, the absorbance or reflectance in the visible range directly affects the perceived color of the chemicals involved.^[10]

The present study revealed the highest sealing ability for Group I, i.e., the MTA group; these observations agree with previous studies. Jeevani *et al.* reported that MTA resulted in superior furcation sealing ability compared to Biodentine. MTA's excellent, unique property is its ability to promote cementum regeneration, thus facilitating the periodontal apparatus's regeneration and excellent marginal adaptation to the perforation sites' external borders.^[11]

In the present study, Biodentine showed sealing ability comparative to MTA. Sinkar *et al.* reported that MTA and Biodentine showed better sealing ability than MTA.^[12] Kokate and Pawar conducted a study to compare the microleakage of glass ionomer cement, MTA, and Biodentine as retrograde filling materials and concluded that Biodentine exhibited the least microleakage when compared to other materials used.^[13]

In the current study, Bioactive bone cement's sealing ability in sealing was equally effective as MTA. This property is because the BG in the presence of simulated body fluid forms a layer of apatite crystals, which nucleate and grow and occupy the space present between the bone cement and dentinal wall at the microscopic level.^[10] From their study results, Demir *et al.* concluded that BG had shown osteostimulatory and osteoconductive properties.^[14] It has been reported that it had an antibacterial effect against subgingival, supragingival bacteria. Sculean *et al.* stated that this material has good clinical manageability and specific hemostatic properties. They assumed that BG might be an ideal matrix in furcal perforations by considering its barrier-like properties.^[15]

Table 1: Mean spectrophotometric dye absorbance values of four different experimental groups

Group	n	Mean	SD	Minimum	Maximum
MTA	10	0.484	0.153	0.264	0.665
BIODENTINE	10	0.555	0.212	0.265	0.966
BIOACTIVE GLASS + BIODENTINE	10	0.686	0.164	0.396	0.976
BIOACTIVE GLASS + MTA	10	0.890	0.060	0.804	0.985

F=12.89; P<0.001

Balachandran and Gurucharan stated that combining two biocompatible materials could produce minimal cytotoxicity and maximum biocompatibility.^[9] In the present study, MTA and Biodentine modified BG to provide a track record favoring factors of repair material. Tests done by various authors^[16,17] for cytotoxicity revealed that fibroblast cells were unaffected by bone cement and biocompatibility of bone cement was similar to MTA. According to Miyazaki *et al.*, bioactivity can be induced in a biomaterial by incorporating silanol (Si-OH) groups and calcium (Ca⁺²) salts.^[18] The Ca⁺² salts start triggering hydroxyapatite formation, while the silane coupling agent may provide a Si-OH group after exposure to simulated body fluid.^[19] The reason for the addition of a silane coupling agent (MPS) was to accelerate apatite formation, maintain mechanical properties and increase the compressive strength.^[18]

The marginal sealing ability of calcium silicate-based materials is attributed to their ability to produce surface apatite crystals when in contact with the phosphates available in tissue fluids.^[20] Han and Okiji compared calcium and silicon uptake by adjacent root canal dentine in the presence of phosphate-buffered saline using Biodentine and ProRoot MTA. The results showed that both materials formed a tag-like structure composed of the material itself or calcium-or phosphate-rich crystalline deposits. The thickness of the calcium and silicon-rich layers increased over time. The thickness of the calcium and silicon-rich layer was significantly larger in Biodentine than MTA after 30 and 90 days, concluding that the dentine element uptake was greater for Biodentine than for MTA. These findings lead to the notion that apatite formation contributes to leakage reduction by filling the gap with the interface and dentine interactions such as intrafibrillar apatite deposition.^[21]

The setting time and handling properties for Biodentine + BG were superior compared with MTA + BG. The possible reason for the reduced sealing ability of BG + MTA might be modifying the bioactive bone cement, which affected the cement's setting time and handling properties of the cement. The exothermic reaction of polymethylmethacrylate bone

cement during its setting has adverse effects. The cement required for perforation repair is significantly less and produces a smaller exothermic reaction much-reduced amount of monomer. A study conducted by Mehrvarzfar *et al.* stated that BG interferes with the adaptation or bonding of the MTA to the tooth structure, leading to the MTA's reduced sealing ability.^[3] This explains the reason for reducing the sealing ability of the MTA bone cement in our study.

Though there are various studies on MTA, Biodentine as furcation perforation repair, our research is unique in assessing these materials in combination with BG as furcation repair materials. Additional *in vitro*, *in vivo* tests and clinical trials, are desirable to elucidate the perforation repair materials' effectiveness.

CONCLUSION

Within the limitations of this study, it can be concluded that MTA had the superior sealing ability when compared with Biodentine, whereas BG with Biodentine showed superior sealing ability when compared with BG with MTA.

Effect of Calcium Hydroxide (CH), Triple Antibiotic Paste (TAP), Nano-sized CH and Nano-sized TAP as Intracanal Medicament on the Push-out Bond Strength of Biodentine: An In-vitro Study

GANGAVARAPU ESWAR KOWSIK¹, ROOPADEV I GARLAPATI², NAGESH BOLLA³, SAYESH VEMURI⁴, CHUKKA RAM SUNIL⁵, KEERTHI PRIYA NANDIPATI⁶

ABSTRACT

Introduction: Root perforations are one of the common procedural errors faced in endodontic procedures. The ideal root repair material must be capable of bonding to the dentin. Calcium Hydroxide (CH) and Triple Antibiotic Paste (TAP) are mostly used for root canal disinfection.

Aim: To evaluate the effect of calcium hydroxide, triple antibiotic paste, nano-sized calcium hydroxide and nano-sized triple antibiotic paste as intracanal medicament on the push-out bond strength of biodentine.

Materials and Methods: The present in-vitro study was conducted in Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur for a period of 1 month (March 2020). A total of fifty maxillary central incisors (n=50) were decoronated, instrumented with ProTaper rotary NiTi instrument followed by peesoreamers up to number 3, and were divided into five groups (n=10). Group I: CH, Group II: Nano CH, Group III: TAP, Group IV: Nano TAP and Group V: Control group. The respective

medicaments were mixed with propylene glycol and placed to the working length. After one week, medicaments were removed using Passive Ultrasonic Irrigation (PUI). Later, samples were sectioned into slices of 2 mm thickness using hard tissue microtome, and biodentine root repair material was placed into lumen of the slices. All the samples were stored for one week at 37°C, then subjected to push-out bond strength test. Data were analysed using one-way ANOVA, Tuckey, Dunnett's Post-hoc test (p-value <0.05)

Results: The highest push-out bond strength values were observed in the group IV (p-value <0.001) and least in the control group. Biodentine showed significantly higher resistance to displacement among the group II (p-value=0.431) and group IV (p-value=0.074) when compared with their conventional medicaments.

Conclusion: Nano Triple Antibiotic Paste and Nano Calcium Hydroxide enhanced the push-out bond strength values of biodentine when compared to their conventional intracanal medicaments.

Keywords: Calcium silicate cement, Endodontic procedure, Nanoparticles, Passive ultrasonic irrigation

INTRODUCTION

The primary rationale behind intracanal medicament is to kill the bacteria inside the root canal and to avert reinfection. Chemomechanical preparation cannot eliminate the bacteria residing deep in the dentinal tubules (Bystrom A and Sundqvist G) [1]. If the root canal is not appropriately dressed with antiseptic medicaments between the visits, the residual bacteria may increase in the same number as it was in the starting stage of the endodontic treatment. Thus the use of effective intracanal medication for disinfection of root canal is necessitated [2].

Nanotechnology provides the advantage of reducing the size of the particles as well as increasing the efficacy of materials with their specific physicochemical characteristics, such as ultrasmall sizes, increased surface area/mass ratio, bactericidal, increased chemical reactivity and bioavailability [3,4]. Nanoparticle size is <100 nm and can reach the complex anatomy of the root canal system. The use of nanoparticulate intracanal medicaments are proven as an effective way to eliminate resistant bacterial strains [4].

Several intracanal medicaments are used to disinfect the root canal during the inter appointment period. Calcium hydroxide is widely used in clinical procedures due to its high alkalinity, better antimicrobial properties, ability to denature the bacterial lipopolysaccharide and tissue dissolving property (Siqueira Jr JF and Lopes HP) [5]. However,

it is ineffective in the elimination of *Enterococcus fecalis*, the most important bacteria in persistent infections and candidiasis infection. It also has disadvantages like prolonged treatment, alteration in the hardness, and demineralisation of dentine. Nano Calcium Hydroxide (NCH) particles are reported for higher levels of antimicrobial activity in comparison with conventional CH and deeper penetration into the dentinal tubules [6,7].

The TAP is a mixture of ciprofloxacin, metronidazole, and minocycline. Initially, its use was recommended by Sato I et al., the proportions of the three antibiotics were recommended in a ratio of 1:1:1 by Hoshino E et al., 3:3:1 (Takushige T et al.) and a 3 Mix MP paste using propylene glycol and macrogol as a vehicle in the ration 7:1; however, the ideal guideline to which to adhere remains a controversy [8-10]. Triple Antibiotic Paste (TAP) also has some of the demerits, like causing tooth discolouration due to the presence of minocycline [11,12]. Karczewski A et al., reported the synthesis of clindamycin modified triple antibiotic nanofibres. In this study, the preparation of nano TAP was done by particle reduction using a ball miller [13].

Endodontic treatment can be complicated and challenging. Some of the iatrogenic errors complicate the outcome of endodontic treatment. Of those mishaps, one of the most commonly encountered procedural errors is a perforation of the root, which

affects the prognosis of the tooth. Ideally, root perforations should immediately be repaired with a biocompatible material to seal the communication with the periradicular tissues. An ideal perforation repair material should provide an adequate seal, be biocompatible, not affected by blood contamination, not be extruded during condensation, able to resist masticatory forces under function, bactericidal, induce bone formation and healing, radio-opaque, induce mineralisation, cementogenesis and easily manipulated for placement [14,15].

Calcium hydroxide, glass ionomer cement, Mineral Trioxide Aggregate (MTA), Hydroxyapatite, etc., are commonly used to manage perforation defects. Among these calcium silicate cements like MTA and Biodentine are emerging in contemporary practice because of their biomimetic properties and ability to withstand moist conditions. Biodentine (Septodont, Saint Maur des Fosses, France) has several advantages over MTA because of better handling properties, increased strength and hardness close to that of natural dentine, smaller particle size, increased micromechanical retention, ability to complete single appointment procedure [16-19].

Interim medicaments should be removed entirely from the root canals to maintain the sealing efficacy of root canal sealers and filling materials. The literature to date suggests that no method was able to remove the intracanal medicament placed in the root canals completely. The frequency of the ultrasonic device is in the range of 20-40 kHz. It has advanced fluid dynamics by the formation of cavitation and acoustic microstreaming that can remove the debris even from the complex anatomy of the root canal system (Goodman A et al.,) [20].

To date, many studies have been attempted to evaluate the effect of different intracanal medicaments on the bonding ability of calcium silicate-based cements [21-23]. None of them were based on the effect of nanoparticle ranged intracanal medicaments. The purpose of this study was to evaluate the effect of conventional TAP, CH, and their nano modified intracanal medicaments, i.e., nano TAP, NCH on the push-out bond strength of biodentine root repair material.

MATERIALS AND METHODS

This in-vitro study was conducted in March 2020 for a period of one month in the Department of Conservative Dentistry and Endodontics at Sibar Institute of Dental Sciences, Takkellapadu, Guntur, Andhra Pradesh, India. The study protocol was approved by the Institutional Ethical Committee (IEC) (Pr.228/IEC/SIBAR/2020).

Inclusion criteria: Maxillary central incisors that were freshly extracted for periodontal reasons also with complete root formation and single canal with $<10^\circ$ curvature, no visible caries, fracture, cracks, resorption, calcifications. The degree of curvature was calculated using the methodology described by Schneider SW [24]. Canal morphology was assessed by buccolingual and mesiodistal radiographs.

Exclusion criteria: Open apex tooth, teeth having more than one canal and $>10^\circ$ curvature, teeth that were having fracture, crack lines, resorptive defects and calcification.

Preparation of nano medicaments: Nano medicaments are prepared mechanically by particle size reduction attained through a ball miller (top-down approach) similar to Zhang W et al., [25]. The average particle size of nano modified intracanal medicaments were analysed using the dynamic laser scattering method as done by Che L et al., in Zetasizer nano Ver.7.12 (Malvern Instrument Co., Southborough, UK) equipped with a He-Ne laser of wavelength 632.8 nm [26].

Specimen Preparation

Fifty maxillary central incisors (n=50) that were under inclusion criteria were selected and disinfected in 0.1% thymol solution for 24 hours and stored in saline until use. All the samples were decoronated

upto cemento-enamel junction using a diamond disc and the apical patencies were checked with a 10 k file (Mani.Inc., Tochigi, Japan). The working lengths were confirmed with radiographs. Root canals of all samples were prepared to the working length by using Protaper (Dentsply Maillefer, Ballaigues, Switzerland) NiTi rotary system to a size F3 using 17% Ethylenediaminetetraacetic acid (EDTA) (Desmear, Anabond Stedman Pharma Research Ltd, India). The canals were irrigated with 2 mL of 3% Sodium hypochlorite (NaOCl) (Prime Dental Products Pvt., Ltd.) after each instrumentation. The samples were then prepared with peesoreamer (Mani, Inc. Ltd Japan) upto a size of number 3 to attain a standardised internal diameter of 1.3 mm. Final irrigation was done with 3% of NaOCl, followed by 17% EDTA to remove the smear layer. The samples were finally irrigated with 2 mL of saline to avoid harmful effects of NaOCl and EDTA and dried with paper points. The samples (n=50) were divided into five groups, as follows:

Group I: Calcium Hydroxide paste (CH) (n=10)

Group II: Nano Calcium Hydroxide paste (NCH) (n=10)

Group III: Triple Antibiotic Paste (n=10)

Group IV: Nano Triple Antibiotic Paste (n=10)

Group V: Control group (n=10)

The respective medicaments in Groups I-IV will be mixed with propylene glycol and placed to working length using a lentulospiral (Dentsply, Konstanz, Germany). No medicament was placed in the control group. The coronal orifices were sealed with a cotton pellet and temporary filling material (Cavit; 3M ESPE, Seefeld, Germany), and the samples were stored for one week in an incubator at 37°C and 100% relative humidity. After one week, the medicaments from group I-IV were removed from the root canals using Passive Ultrasonic Irrigation (PUI). A 15 U file was used, which was kept 2 mm short of working length and agitated for 30 seconds duration at a power setting of 6. Distilled water was used as an irrigant in PUI followed by 5 mL of NaOCl irrigation and a final flush of 5 mL of distilled water. The samples were sectioned perpendicular to the long axis to obtain 2 mm slices from the middle third of the root from each sample using hard tissue microtome (Isomet; Beuhler Ltd., NY, USA) so that from each group a total of 10 slices were taken from 10 samples.

The biodentine root repair material was mixed according to the manufacturer's instructions, i.e., liquid from a single-dose container was emptied into a powder-containing capsule and mixed for 30 seconds at 4,000-4,200 rpm. It was incrementally placed into canal spaces of dentine slices being placed on a glass slab and condensed with a hand plugger. Excess material was removed from the surface of samples with a plastic instrument. The specimens were stored in an incubator at 37°C in 100% relative humidity for one week.

Push-Out Test

After one week, the samples were subjected to push-out bond strength analysis using Instron AutoGraph AG15 universal testing machine (Shimadzu, Japan) [Table/Fig-1]. Samples were placed on a custom made metal slab with a central hole. It was aligned with the centre of the test sample, which allowed the stainless steel stylus of the machine to pass freely once the bond between the test material and tooth was broken. The plunger was placed such that it had only minimum clearance with the sample to ensure contact with test material only. A stainless steel needle with 1 mm diameter was used to apply the compressive load with downward pressure on the surface of test material at a speed of 1 mm/min. The maximum force at the time of dislodgement was recorded in Newtons. The push-out bond strength was calculated in MPa by using the formula Push-out Bond strength (MPa)=debonding force (N)/surface area ($2p \times r \times h$) in mm^2 , where 'p' is the constant (3.14), 'r' is the root canal radius, and 'h' is the thickness of the root dentine slice in millimetres [27].

[Table/Fig-1]: Push-out test.

STATISTICAL ANALYSIS

Data were entered in MS-Excel and analysed in Statistical Package for the Social Sciences (SPSS) version 21.0. Shapiro Wilk test was applied to find normality. Descriptive statistics were represented by Mean with Standard Deviation (SD). A 95% confidence intervals were calculated. One-way ANOVA, Tuckey, Dunnet post-hoc test were applied to find significance. p-value <0.05 was considered statistically significant.

RESULTS

[Table/Fig-2] represents the mean values and standard deviation of push-out bond strength (MPa) of all groups. The mean highest push-out bond strength values were observed in group IV i.e., 12.33 MPa (p-value <0.001) and least in the group V i.e., 3.32 MPa. Biodentine showed significantly higher resistance to displacement among the group II (p-value=0.431) and group IV (p-value=0.074) when compared with their conventional medicaments [Table/Fig-3].

Group	Minimum	Maximum	Mean	SD	Median	IQR	p-value
Group I	2.34	12.03	6.54	3.13	6.25	4.28	<0.001
Group II	6.09	13.13	8.65	2.39	7.81	3.95	
Group III	5.63	15.78	9.03	2.88	7.88	3.18	
Group IV	6.88	15.01	12.33	2.95	12.97	4.09	
Group V	3.25	3.41	3.32	0.07	3.31	0.12	

[Table/Fig-2]: Mean push-out bond strength values and Standard Deviations (SD) of all test groups.

(One-way ANOVA, Tuckey, Dunnet post-hoc test were applied to find significance. p-value <0.05 was considered statistically significant)

Intergroup comparison		p-value
Group I	II	0.431
	III	0.269
	IV	<0.001
	V	0.292
Group II	I	0.431
	III	0.998
	IV	0.036
	V	0.017

(One-way ANOVA, Tuckey, Dunnet post-hoc test were applied to find significance. p-value <0.05 was considered statistically significant)

DISCUSSION

Root repair materials should adhere well to root canal dentine and offer significant resistance during the function in the oral cavity. There are various bond strength tests like tensile, shear, push-out bond strength to study the adhesive property of root repair materials to the dentine. In the present study, the push-out bond strength test was used, as it is a reliable, efficient, and practical method [27-29].

Chou K et al., and Berkhoff JA et al., reported that removing intracanal medicaments entirely is a challenge because of their penetration and binding to root canal dentine [30,31]. Calt S and Serper A reported that the residual intracanal medicament affects the penetration of obturating material into the root canal dentine [32]. Margelos J et al., confirmed the interaction of residual intracanal medicaments with zinc oxide based sealers affecting the quality of the sealer and Ozturk TY et al., reported formation of more voids during the marginal adaptation of biodentine with root canal wall [33,34].

In the present study, PUI with distilled water, NaOCl as irrigants using stainless steel 15 U file keeping 2 mm short of working length was performed to remove the intracanal medicaments. This method enables better acoustic streaming of the irrigants producing micro cavitation bubbles within the root canals (Van der Sluis LW et al.) [35]. The effect of intracanal medicaments on the bond strength of root repair materials are critical because they affect the penetration ability of calcium silicate-based cements into the root canal dentine and formation of tag like structures and mineral infiltration zone by hindering calcium silicon ion exchange with the dentine [16].

In this study, the push-out bond strength values of Biodentine were higher in the nano TAP (group IV), followed by TAP (group III) when compared to other groups. Nano medicament groups showed significantly higher bond strength values when compared to their conventional counterparts. The results of the present study were in accordance with Tulumbaci F et al., who reported that the binding of residual minocycline to the calcium via chelation might have increased the push-out bond strength values of TAP [36]. On the contrary, Shaheen NA et al., found that intracanal medicaments have no significant effect on the bond strength values of biodentine. TAP causes excessive demineralisation of the dentinal surface, which might be the reason for the significant difference in the TAP group causing better penetration of the biodentine in our study [37]. The residues of intracanal medicaments shown to decrease the micromechanical interlocking properties of these cements. In the present study, the least mean pushout bond strength in the control group (saline) might be due to the interaction of residual NaOCl with the biodentine affecting the adhesion of calcium silicate based biodentine [38]. Pereira AC et al., found no significant effect of intracanal medicament on bond strength of biodentine when compared with chlorhexidine, TAP, distilled water and control groups [39]. However, they detected small amounts of phosphorous ions in the triple antibiotic group

at their interface. The higher bond strength of biodentine was due to the small particle size and high flowability of biodentine, which might have improved the penetration of the material into the dentinal tubules, increasing bond strength when compared to MTA group in their study. The powder of biodentine is composed of tricalcium silicate, calcium carbonate, zirconium oxide and the liquid part contains water and calcium chloride as a setting accelerator and a hydrosoluble polymer as water reducing agent, which improves the physical and handling properties of this material [40].

In the present study, the NCH (group II) had shown better push-out bond strength values when compared with the CH (group I); however, these were inferior when compared to group III and IV. Propylene glycol was used as a vehicle in the present study, which might have negatively affected the carbonation reaction of CH with the environment, study by Cruz EV et al., [41]. The results of the present study are in accordance with Guiotti FA et al., who reported that CH remnants reduces the bond strengths of calcium silicate-based cements [42]. Yassen GH et al., reported that disruption of dentinal collagen occurs due to the high alkaline pH of CH [43]. This affects the bond between hydroxyapatite and collagen fibrils of dentine, which in turn decreases the push-out bond strength of biodentine. It might be the possible reason for the lesser push-out bond strength values of CH when compared to nano and conventional TAP. The study done by Nagas E et al., reported a higher bond strength of biodentine with CH group when compared with TAP [23]. It was due to the smaller particle size of biodentine and better penetration ability.

The possible reason for better push-out bond strength values of nano modified medicaments in the present study when compared with the conventional groups might be due to the size of nano medicaments less than 100 nm. Nano medicaments might be easily dislodged on the ultrasonic activation leading to better bonding with the exposed dentinal tubules in the root canal wall. So lesser remnants cause better exposure of dentinal surface, enhancing the tag like structures of biodentine which might have increased resistance to dislodgement study by Aggarwal V et al., [15].

The difference in bond strengths of biodentine might also be due to experimenting maxillary incisors, usage of the viscous vehicle for the medicaments, and experimental design, affecting the bond strength values of biodentine when compared with previous studies by Alsubait S et al., Nagas E et al., Tulumbaci F et al., [21,23,36].

Limitation(s)

Although it is not always possible to generalise the results of in-vitro studies in the clinical scenarios. In the present study, the authors have considered the application of ultrasonics in comparing the effect of residual intracanal medicaments on push-out bond strength of biodentine. Further studies are necessary to substantiate the findings of this research and also the removal efficacy of ultrasonic agitation on nano-sized intracanal medicaments and highlight their importance in endodontic treatment.

CONCLUSION(S)

Within the limitations of the present study it can be concluded that nano-sized medicaments can be efficiently used as intracanal medicaments as alternative to conventional medicaments because of improvement in the push-out bond strength values of biodentine. CH, NCH, TAP and nano TAP have enhanced the push-out bond strength values of biodentine. Nano TAP had shown highest mean pushout bond strength values when compared to other groups. NCH and nano TAP had significantly improved the push-out bond strength values when compared to CH and nano TAP respectively.

ABSTRACT

Antioxidants are a group of natural phytochemicals found in dietary ingredients that can be utilised to treat oral lesions and diseases. They are employed as chemical compound alternatives since they have less adverse effects. The dietary antioxidants found in fruits and vegetables reduce the damage by modulating detoxification enzymes, increasing immune system, and hormone metabolism. Scientists were drawn to antioxidants because of their ability to modify cell cycle controls, apoptosis, invasion, angiogenesis, and metastasis. They have demonstrated significant success as single treatments or in combination with chemo-preventive medicines for oral lesions.

Inside this article, we will look at the immuno-modulating effects of antioxidants, which aid in the treatments and even sometimes avoidance of numerous oral and maxillofacial conditions that contribute to morbidity, such as autoimmune lesions, and death, such as oral cancer. Antioxidants are chemicals that considerably impede or decrease the degradation of a living matter and defend the organism from oxidative harm. As a result, the sickness will be significantly reduced.

Keywords: Antioxidants; Phytochemicals; Phenolics; Beta-carotene; Tocopherol; Cyanins; 13-Cis-retinoic Acid (Isotretinoin); Apoptosis; Autoschizis; EGCG (Epigallocatechin Gallate)

1. Antioxidants classification: First classification

1.1 Antioxidants enzymatic

Superoxide dismutase, catalase, glutathione peroxidases, malonaldehyde, glutathione reductase, and glutathione transferase.

1.2 Antioxidants non-enzymatic

1) Nutrient—alpha tocopherol, vitamin A, beta carotene, vitamin E, ascorbate, glutathione, selenium.

2) Non-nutrient—ceruloplasmin, transferrin, uric acid, peptides, camosine.

2. Second classification

Antioxidants found in nature—can be distributed into the following categories:

1) Enzymes, such as superoxide, hydroxyl, and glutathione peroxidase.

2) Low molecular weight antioxidants—these are additionally classified as:

- a) Tocopherol, carotenoids, bilirubin, and certain polyphenyl antioxidants are examples of lipid-soluble antioxidants.
- b) Water-soluble antioxidants such as ascorbic acid, uric acid, and polyphenyls.

3. Phenolics

Phenolics occur by far the most abundant phytochemical class and are found throughout the plant world. Flavonoids, phenolic acids, and polyphenols are the three major classes of nutritional phenolics. These were all hydroxyl group (-OH) containing chemical substances in which the (-OH) is directly connected to an aromatic hydrocarbon chain. In the category of natural substances, phenol (C₆H₅OH) is considered a basic class. They are plant's secondary metabolites that play a vital function as defence chemicals. Phenols have various beneficial qualities for beings, and their antioxidant capabilities are significant in identifying their role as anti-free radical-mediated disease processes. Flavonoids are the most well-known and biggest category of plant phenols. Phenolics are also classified as a broad category that includes the commonly utilized hydroxyl-benzoic and hydroxyl-cinnamic acids. Phenolic polymers, often referred as tannins, are high-molecular-weight substances classified in two main types: hydrolysable tannins and condensed tannins.

Flavonoids are polyphenolic chemicals found throughout ecosystems. Over 4,000 flavonoids have been identified, several of which are found in veggies, fruits, and consumables such as teas, coffee, and juice drinks. Those seems to have played a great effect in medical achievements from ancient times. They can be found in vascular vegetation as glycones, glucosides, and methylated compounds. Additionally, 4,000 flavonoids have been encountered in plant components ingested by mankind, with roughly 1,030 flavanols and 650 flavones being widely recognised. Flavanoids like as luteolin and catechins are more powerful antioxidants than nu-

trients such as vitamin C, vitamin E, and beta-carotene^[1].

Many therapeutic qualities have been claimed for them, including enzyme inhibition, anti-inflammatory activities, antimicrobial activities, anti-allergic activities, estrogenic action, powerful antioxidant action, vascular function, and cytotoxic anticancer activity. They are a diverse group of chemicals that play a crucial role in shielding raw mechanisms against the damaging effects of oxidation process on critical supermolecules such as carbs, proteins, lipids, and Genetic material.

4. Terpenoids (Terpenes)

Terpenes, commonly referred as isoprenoids, are the most abundant phytonutrient class in plant foods, soy plants, and grain. The significance of such terpenes to plants derives to their need for carbon via photosynthetic activity involving photosensitizing compounds. They are oligomers and polymers centered on photo-reactive chemistry. Terpenes were indeed tanins with just a heterogeneous group of high molecular mass polyphenolic molecules and the ability to form mutable and irrevocable developments with proteins (primarily), polysaccharides (cellulose, hemicellulose, pectin, etc.), alkaloids, nucleic acids, and natural resources, among other things. Based on its structural and chemical properties, tannins may be classified into four distinct categories: gallo tannins, ellagitannins, complicated tannins, and condensed tannins. Tannin-containing plants are often used as astringents, diuretics, and stomach and duodenal remedies.

5. Beta-carotene

Spinach, carrot, sweet potato, mangoes, papaya, and oranges are high in beta-carotene, a natural vitamin A precursor.

Beta-carotene's actions include:

- Antioxidant free radical reduction/elimination.
- Immuno-modulation-promotion of a rise in cell-reconciled immune reaction (T-helper, NK cells, and cells with IL-2 receptors) as a result of enhanced monocytes expression and tumour necrosis

factor-alpha activity.

- Mutagenesis inhibition.
- Cancer cell growth inhibition^[2].

In places with low oxygen concentrations, beta-carotene is also employed to scavenge able radicals like peroxy and hydroxyl radicals. Serum beta-carotene concentrations have been demonstrated to decline in several oral premalignant lesions and disorders, and due to its supplementation (30 mg/day) has resulted in lesions reduction. As per Liede *et al.*^[3], a beta-carotene-enriched diet can help avoid alterations in the oral mucosa, particularly in smokers, who have lower blood amount of vitamin C and beta-carotene than non-smokers. In one trial, 23 individuals with oral leukoplakia have been given beta-carotene in oral dosages of 90 mg/day for three months. A third of the 18 individuals who finished the research had a full clinical recovery. No details or clinical signs of poisonousness were observed in several of the patients.

5.1 Adverse effects

Portion of the beta-carotene stored in fatty tissue serves as the reserve form of vitamin A and can be split into this vitamin in the event of a deficiency. To maximise benefits and minimise damage, dose evaluation in future research must be based on known knowledge. Two large-scale trials found deleterious effects when beta-carotene dosages exceeded 20 mg/day. The content of many other antioxidant in the organism is likewise affected by selective carotene supplementation. High dosages of carotene increase plasma concentrations of beta-carotene, lycopene, and vitamin E while decreasing lutein and zeaxanthin levels.

6. Retinoic acid (vitamin A)

Retinoic acid is found in carotene and poultry meat, milk, and eggs. Furthermore, retinoic acid is processed into retinal in the gut, and retinol and hypervitaminosis develop while ingestion surpasses the liver's capacity to retain retinoids. Vitamin A is essential for the correct differentiation of epithelial cells. Retinoids' impacts on gene expression have been shown to alter the proliferation and development of normal cells and cancer cells *in vitro*.

Because retinoids promote apoptosis, which leads to proper cell maturation, and prevent carcinogenesis, they have been studied in the regulation and control of carcinogenesis. It has also been shown that epithelial cells grow slower after being exposed to retinoids^[1].

Changes in enzyme activities and DNA alterations caused by free radical reactions increase the chance of establishing cancerous cell lines. Reducing free radicals with antioxidants like vitamin A may help to avoid such cellular alterations. A link has been shown between vitamin A deficiency and an increased susceptibility to carcinogenesis, with an increased chance of developing various epithelial carcinomas of the lungs, colon, pharynx, larynx, and oesophagus. Isotretinoin (13-cis retinoic acid) may inhibit the formation of leading squamous cell carcinoma. Treatment with 13-cis retinoic acid (Isotrenitin) can restore the production of retinoic acid receptors (RAR) mRNA, which itself is lost in pre-malignancy, indicating a hopeful response to the treatment^[2].

- Inhibits keratinization and epidermal cell terminal differentiation; improves cellular immunity.
- Stops or slows the development of leukoplakia.
- Causes cancer cells to be cytotoxic and cytostatic.
- Has an impact on DNA, RNA, and gene function^[3].

It was recommended that individuals with a large premalignant oral lesion start with 50 mg of 13 RA/d. Shah *et al.*^[4] cured 16 affected individuals having oral leukoplakia given topical dosages of 13-cis retinoic acid (Isotrenitin) ranging from 3 to 10 mg/day administered as lozenges for six months. 5 (31.2%) of the individuals discontinued participation due to adverse effects, while two of the three patients who demonstrated complete clinical remission experienced relapses within 5 weeks after stopping the drug. In oral leukoplakia, Stich *et al.*^[5] investigated combination beta carotene and retinol, beta-carotene alone, and palliative, yielding full response rates of 27.5 percent, 14.8 percent, and 3.0 percent, respectively.

6.1 Adverse effects

Toxicities at preventive dosages include skin rash, nasal mucosal dryness and bleeding, conjunctivitis, oral mucositis, cheilitis, hyper-tri-glycerinemia, and teratogenic consequences. Topical treatment provides the potential benefit of delivering a high local dosage with less systemic exposure, reducing the risk of systemic adverse effects. The topical treatment, on the other hand, necessitates patient motivation and the capability to cooperate with repetitive local applications. Furthermore, topical administration may be problematic in some areas, and the drug may well be weakened by saliva. Because of the acid medium of the topical preparations or the base in which the drug is put, local tissue irritation in the form of tissue sensitivities and burning may occur with current topical administrations^[2].

7. Lycopene

It is a red, fat-soluble pigment produced by plants and microbes. Millard found it in 1876 and extracted it from other red fruits and vegetables, such as rose grapefruits, melons, pink guavas, and apricots. Apart from these, it is found in fungi and algae. It is the non-cyclic isomer of beta-carotene, which is essentially a carotenoid. It is among the most powerful antioxidants available. Lycopene, unlike most of the other carotenoids, does not exhibit pro-vitamin A activity. In a three-month double-blind, placebo-controlled randomised controlled experiment undertaken by Singh *et al.*^[6], lycopene supplementation at 4 mg and/or 8 mg per day reduced hyperkeratosis in 80 percent of patients. Complete clearance of the lesions was observed in 55% of individuals receiving 8 mg/day and 25% of those receiving 4 mg/day. Lycopene was identified as a viable therapy option in a comprehensive evaluation of antioxidants in the cure of different leukoplakia. Gupta *et al.*^[7] discovered that eating tomato—the primary source of lycopene—has a preventive effect on oral leukoplakia when researching the link of certain nutrients and dietary products with oral precancerous lesions. It has happened proven to limit the growth of KB-1 human being oral tumour cells by regulating connex-

in-43 (gap junction proteins) levels, resulting in increased gap-junctional communication. The average daily consumption of lycopene is calculated to be 3.7 mg^[1].

A three-month randomised controlled experiment done by Zakrzewska *et al.*^[8] indicated clinical and functional improvement in individuals with oral leukoplakia treated with 4 mg and/or 8 mg lycopene per day. Positive histological alterations were also seen in individuals receiving 8 mg of lycopene per day^[8].

7.1 Adverse effects

Large amounts of dietetic consumption have no negative impact on an individual's wellbeing. To present, there is no evidence of lycopene treatment-related adverse effects or systemic toxicity. According to numerous safety investigations, no negative effects were observed at the greatest consumption amount, 5 g/kg/day^[8].

8. L-ascorbic acid (vitamin C)

Citrus fruits including kiwi, strawberries, papayas, and mangoes contain L-ascorbic acid (L-AA), often recognized as vitamin C. Adults in the United States should consume about 100 and 120 milligrammes of ascorbic acid per day. In the event of smokers, a daily consumption of almost 140 mg/day may lower L-AA concentrations in serum white cells. L-AA has had an anti-oxidizing function and interacts with superoxide generated by the cells' regular metabolic activities; this superoxide inactivation reduces the synthesis of nitrosamines throughout protein breakdown and helps to avoid damage to cellular DNA and cellular proteins. Other than being an antioxidant, L-AA does have the following influences:

- Slows the deterioration of vitamin E.
- Increases the activity of chemotaxis, phagocytosis, and collagen formation.
- Prevents the production of nitrosamines.
- Improves detoxifying via cytochrome P450.
- Prevents the production of fecal mutagens.
- Lowers oncogene expression^[4].

9. Alpha-tocopherol

Vitamin E refers to a trio of organic compounds that are substantially linked to alpha-tocopherol. Natural forms of vitamin E include four tocopherols, alpha, beta, gamma, and delta tocopherols, and four tocotrienols, alpha-, beta-, gamma-, and delta- tocotrienols. The most prevalent and effective form of vitamin E is alpha-tocopherol (AT). It can be found in vegetable oil, margarine, and green plants. The daily advised limit rates for male adults are 10.00 mg/day and 8.00 mg/day for grownup females^[4].

Ribeiro *et al.*^[9] investigated the toxicity and effectiveness of vitamin E in 43 individuals with OL using 400 IU twice each day for 6 months and discovered that ten patients (23%) had detailed clinical remission of lesion and 10 patients (23%) had a moderate clinical response. Tocopherol is an efficient antioxidant at elevated oxygen levels, shielding cellular membranes from lipid peroxidation. A dose of 800 IU/day for 6 to 9 months was regarded acceptable for chemoprevention of oral leukoplakia. AT's primary actions are as follows:

- Scavenging of free radicals.
- Membrane integrity and immune function regulation.
- Cancer cell progression/differentiation inhibition.
- Cytotoxic activity.
- Preventing mutagenicity and the generation of nitrosamines.
- Preventing the synthesis of DNA, RNA, and proteins in cancer cells.

Vitamin E has been recommended as an antioxidant in oral lesions by Chandra Mouli *et al.*^[10] Tobacco-specific nitrosamine (carcinogens) undergo a unique activation and detoxifying mechanism, which vitamin E can block. It has the potential to avoid oral cancer at an experimental stage, in premalignant lesions and premalignant situations. Many previous research show that antioxidants (vitamin E) can be used to treat oral mucosal diseases such as oral leukoplakia, oral lichen planus, oral submucous fibrosis, and oral cancer. In animal models, vitamin E shows synergistic inhibitory action against carcinogenesis and may have some

therapeutic benefits in humans. Many research employing vitamin E in oral leukoplakia found a good clinical response in 46% of 43 patients after 24 weeks, as well as a histological response with no major side effects. Another study discovered a substantial reduction for oral leukoplakia after combining vitamin E, retinol, and beta-carotene therapy^[8]. As a result, it shows promise for the treatment of leukoplakia.

9.1 Adverse effects

Synthetic vitamin E dosages utilised in antioxidant treatment may raise legitimate concerns, because in the United States, for example, 300 mg/d is the highest acceptable daily dosage of this supplement, and 2 g/d is already deemed hazardous. In comparison to vitamins A and D, vitamin E is only ostensibly harmless, i.e. somewhat non-toxic. When used in high doses, it can cause adverse effects (most notably during injections) by inhibiting 5-lipoxygenase in blood platelets and leucocytes (resulting in inadequate synthesis of thromboxane and leukotrienes), diminished blood coagulability (due to excessive suppression of platelet activation), and interruption of granulocyte and phagocyte anti-infective function relying on responsive oxidants.

10. Vitamin K

It is a fat-soluble 2-methyl-1, 4-naphthoquinone family that includes phyloquinone (K1), menaquinones (K2), and menadione (K3). One study discovered that vit K1 doses of 100–300 ng/ml inhibited cell proliferation. Vitamin K2 has been demonstrated to function at the cell cycle level, inhibiting the cell growth and initiating differentiation by acting on cyclins. The cytotoxic activity of vitamins C and K3 is characterised by autschizis, a cell death that is anatomically different from apoptosis and necrosis.

11. Green tea

Green tea polyphenols' anti-carcinogenic properties, primarily EGCG (epigallocatechin-3-gallate), the most biologically active catechin, are likely inhibiting the activity of tumor for-

mation and advancement, induced apoptosis, and inhibition of cell reproduction rates, all of which slow tumour growth and development. Green tea polyphenols' antioxidant capacity is directly tied to the aromatic rings and hydroxyl molecules that comprise their structure, and is a result of the hydroxyl groups' binding and neutralisation of free radicals. Epigallocatechin-3-gallate arrests cells in the G0-G1 stage, downregulates cyclin D1, increases p14ARF and/or p16 protein content, therefore stabilising p53 and regulating apoptosis, and inhibits angiogenesis by lowering VEGF phosphorylation and inhibiting VEGF release by tumour cells. Green tea extract used topically has been demonstrated to diminish the severity of oral leukoplakia^[4].

11.1 Adverse effects

Green tea has positive effects, however, excessive use of green tea has been linked to possible negative effects. Caffeine is a primary component, and consuming over than 5 cups of green tea per day may result in sleeplessness, restlessness, and stomach distress. It has been noticed that green tea is used for weight loss, therefore high quantities of caffeine may induce significant negative effects. Green tea should be used with caution for this purpose. Tannins found in green tea, such as catechin and epicatechin, bond with non-heme iron in human blood. This inhibits absorption of iron, which can result in iron deficiency anaemia. Iron deficiency anaemia can induce fatigue, breathlessness, irritability, headaches, and irregular heartbeat. It also includes vitamin K, which is why excessive use of green tea is discouraged, and individuals on warfarin, aspirin, or anticoagulants may prevent blood clotting^[11].

12. Neem

Gallic acids, catechin, and epicatechin are phytochemicals linked to oral cancer that include glutathione, a carcinogen-detoxifying enzyme. Catechin can block the formation of metalloproteinases, limiting cancerous cells invasion and migration and triggering death. It has anti-inflammatory properties by inhibiting the activity of nuclear factor-b

(NF-b), which causes tumor cells to die. It is antibiotic, antifungal, antihelminthic, anticancer, anti-inflammatory, and neuroprotective. It is used in mouthwashes to treat aphthous ulcers. Neem leaf extract has been linked to the treatment of oral cancer. It is available in both dry and oil forms^[12].

13. Curcumin

Curcumin is a bright yellow phenolic compound derived from turmeric. It is a perennial herb of the Zingiberaceae family. It has been utilised for generations in Indian conventional medical treatment for its anti-inflammatory properties. Its principal ingredients are three curcuminoids, including curcumin (the vital element and the one accountable for its yellow coloring and anti-inflammatory properties due to the compounds demethoxycurcumin and bis demethoxycurcumin). It is well-known for its anti-carcinogenic as well as other curative potential. Turmeric's active ingredients are the flavonoid curcumin (diferuloylmethane) and several volatile oils such as tumerone, atlantone, and zingiberone. Sweeteners, proteins, and resins are some of the other components.

Curcumin, which makes about 0.3–5.4 percent of raw turmeric, is the most well explored active ingredient. It has anticancer effect in the oral cavity, inhibiting cell proliferation and induction of apoptosis in oral tumor cells. It is also linked to notch-1, nuclear factor b (NF-b), and cyclooxygenase-2 (COX2), liquid oxygen (LOX), iNOS (inhibitory nitric oxide synthase), matrices metalloproteinase 9 (MMP-9), tumour necrosis response (TNF), chemokines, various cell-surface adhesion molecules, and cyclin D1 expression. It can boost the effectiveness of cancer therapy with cancer necrotic factor apoptosis-inducing ligand (TRAIL). Curcumin applied twice weekly towards the buccal pouches of Syrian golden hamsters inhibits DMBA-induced oral carcinogenesis. A daily dosage of up to 10 g is indicated to decrease tumour development, progression, and metastasis. Because oxidative stress can play a role in the pathophysiology of Oral Lichen Planus, and Oral Lichen Planus is a chronic inflammatory illness, herbs with both anti-inflammatory and antioxidants qualities may be

effective in controlling Oral Lichen Planus^[13].

13.1 Adverse effects

Researchers have identified unfavourable side effects connected with this polyphenol. Lao *et al.*^[14] performed a dose-escalation research in 34 healthy volunteers to establish the maximum tolerated dosage and tolerability of a sole oral dose of curcumin. The participants were given escalating dosages of curcumin varying from 500 to 12,000 mg, and their safety was evaluated 72 hours later. The experiment had twenty-four participants, seven of whom had mild toxicities that did not show up to be dose-related. These seven subjects particularly reported diarrhea, headache, rashes, and yellow stool. Curcumin at dosages varying from 0.45 to 3.6 g/day for 1 to 4 months was related with nausea and diarrhea, as well as an increase in blood alkaline phosphatase and lactate dehydrogenase levels in humans, according to another research. Curcumin dosages more than 8 g/day were unacceptably high in individuals with higher or premalignant lesions due to the bulky size of the pills. As a result, further research is needed to assess the long-term toxicity of curcumin before it could be licenced for human usage. It is generally regarded as harmless, however it may induce gastric irritation, stomach discomfort, nausea, diarrhea, allergic skin response, and anti-thrombosis activity that interferes with blood clot formation.

14. Cyanidins from grapes

Cyanidin is a pigment extract found in red berries such grapes, blackberries, cranberries, raspberry, apple, plum, red cabbage, and red onion. It has antioxidants and radical scavenging properties that may lessen the risk of cancer. It has been shown to decrease cell growth as well as the expression of the iNOS and COX-2 genes in colon carcinoma cells. Another research confirms this. According to Elattar *et al.*^[15], resveratrol in concentrations comparable to those found in red wines is an efficient regulator of oral squamous cell cancer cell growth and proliferation, hence contributing to its anti-tumor impact. Casto *et al.*^[16] investigated the efficacy of berry extracts to suppress the reproduction of

human tumour cells. According to research done by Selvendiran *et al.*, piperine has greatly extended its chemopreventive action by modifying lipid peroxidation and increasing antioxidant defence^[17].

15. Gingerol from gingers

Gingerol is the essential constituent of fresh ginger that gives it its characteristic spiciness. Ginger contains 1%–4% essential oils and an oleoresin, as well as zingiberene, curcumin, sesquiphellandrene, bisabolene, monoterpenoid aldehydes, and alcohols. It is antibacterial, anti-inflammatory, and analgesic. It has been examined for its anti-cancer properties in tumours of the colon, breast, ovary, and pancreas. Oyagbemi *et al.*^[18] have outlined the processes behind gingerol's medicinal actions. It reduces iNOS and TNF-alpha production by inhibiting IκBα phosphorylation and NF-κB nuclear translocation. When K562 and MOLT4 cells were treated with gingerol, the levels of ROS were much greater than in the control groups, triggering leukaemia cell death via the mitochondrial route. Gingerol and 6-shogaol were discovered to have anti-invasive effect against hepatoma cells by control of MMP-9 and TIMP-1, and 6-shogaol also controlled urokinase-type plasminogen activity in human hepatocarcinoma cells. Single dose of 6-shogaol, other active component of ginger, is more efficient than 6-gingerol and curcumin in suppressing TPA-induced expression of iNOS and COX-2 transcriptional activity in mouse skin, suggesting that additional *in vitro* and *in vivo* research is required. It is used to treat oral thrush as a sialogogue and to reduce toothache. Ginger may lessen the chemotherapeutic agent's toxicity^[13].

15.1 Adverse effects

Although the plant extracts seem to be quite safe, the most common adverse effects that have been recorded include headache, dizzy, agitation, nauseous, vomiting, diarrhoea, and cutaneous sensitivity. Ginkgo has been shown to suppress platelet-activating factors and to shorten bleeding times. As a result, caution was suggested among persons or individuals on anticoagulant treatment. This should not be taken during pregnancy or in

people suffering from biliary illness. Since ginger can interact with blood coagulation, it should be taken with caution in individuals taking anticoagulants like Coumadin or heparin^[12].

16. Capsaicin

Other compounds obtained from plants for spices, in addition to curcumin, have anti-cancer properties. Capsaicin, a spicy ingredient of pepper plants, is widely acknowledged to have anti-cancer characteristics, reducing growth and induction of apoptosis in a broad variety of human tumor cell lines, however, its genotoxic and cancerous capabilities have also been described in multiple papers. Capsaicin has been shown to decrease TPA-induced NF-B activation by inhibiting IB breakdown and consequent nuclear translocation of NF-B/p65. It also inhibits TNF- and TPA-induced adherence of AP-1 and NF-B to DNA binding sites in sentient leukaemia cells and causes apoptosis in human mammary epithelial cells by inducing JNK1 and p38 and depressing ERK. Furthermore, capsaicin therapy inhibits VEGF-stimulated angiogenesis via inhibiting VEGF-induced p38 MAPK and Akt stimulation. In a rodent study, capsaicin administration significantly increases the activity of phase II enzymes such as glutathione S-transferase and quinone reductase in the liver and colon of experimental F344 rats and reduces the advancement of azoxymethane (AOM)-induced colon pre-malignant lesions, aberrant crypt foci (ACF), as well as adenocarcinoma. Tanaka *et al.*^[19] also demonstrated that capsaicin supplementation inhibits chemically induced tongue tumorigenesis in male F344 rats. Capsaicin is a painkiller used in topical application to treat neuropathic pain due to its analgesic action. Capsaicin thereby desensitises stimuli produced by heat, chemical, and mechanical sources. Capsaicin has been proven in studies to be beneficial in people suffering from burning mouth syndrome.

16.1 Adverse effects

Capsaicin has an impact on skin (irritant, sensitizer), eye (allergen), ingestion, and inhaling (lung irritant, lung sensitizer). In mice, the LD50 is 47.2 mg/kg. Painful capsaicin-containing pepper expo-

sure are one of the most regular plant-related exposures reported to poison control centres. They induce searing or stinging discomfort to the skin and can cause nausea, vomiting, stomach pain, and blistering diarrhoea if consumed in large doses by adults or tiny amounts by children. Excessive tears, discomfort, conjunctivitis, and blepharospasm result with eye exposure.

17. Garlic

Garlic is a biological active ingredient that is utilised in Ayurveda to treat a variety of ailments. Allicin, the main component of garlic, is thought to have anti-inflammatory and immunomodulatory activities. Allicin has been shown to significantly reduce inflammatory product release, neutrophil migration, and bacterial and viral inhibition. They also inhibit oxidation and play an important role in immunological regulation. According to one study, allicin can be an efficient pain reliever, promote ulcer healing, and prevent the relapse of recurrent aphthous stomatitis.

17.1 Adverse effects

It has been observed that garlic extract causes a burning feeling in the gastrointestinal system, nausea, diaphoresis, and light-headedness. These extracts may also induce contact dermatitis, and excessive garlic consumption has indeed been linked to severe spontaneous spinal epidural hematoma.

18. Aloe vera

For millennia, people have recognised and used the *A. vera* plant for its medical and cosmetic qualities. The term *A. vera* is derived from the Arabic term *alloe*, which means bright bitter material, and *vera*, which means truthful in Latin. *A. vera*, the wonder plant, has been shown to be advantageous in a variety of health functions. Vitamins, enzymes, minerals, carbohydrates, lignin, saponins, salicylic acids, and amino acids are among the 75 potentially active ingredients. Vitamins A (beta-carotene), C, and E are present and act as antioxidants, helping to neutralise free radicals.

18.1 Adverse effects

In sensitive people, the detrimental consequences of aloe on a topical treatment may produce redness, burning, stinging, and, in rare cases, widespread dermatitis. Anthrax quinones including such aloin and barbaloin cause the majority of allergic responses. It is important to try it on a tiny area initially to rule out any allergic responses. Abdominal pains, diarrhoea, crimson urine, hepatitis, dependence, or deepening of constipation result with systemic ingestion of aloe vera. Long-term usage has been linked to an increased risk of colorectal tumor. Electrolyte imbalances may occur as a result of the laxative impact (low potassium levels).

19. Conclusion

Antioxidants are crucial in the treatment of numerous oral lesions and disorders, acting as a key adjuvant in halting the malignant potential of these illnesses. Thorough understanding of these phytochemicals is essential for clinicians in order to avoid the chronicity of lesions and hence reduce morbidity and death in patients with any recognised oral illness.

Conflict of interest

The authors declare no potential conflicts of interest.

Background: To evaluate the association between stress and periodontitis in different professional college students. **Subjects and Methods:** The study was conducted in 360 professional college students which includes Medical, Dental, Pharmacy, Nursing, Engineering, and Chartered Accountancy. From each group, 60 students were included in the study. Self-reported Depression, Anxiety, and Stress Scale questionnaire was given to all the students and clinical examination was conducted in all the participants to assess the Oral hygiene index - simplified (OHI-S), clinical attachment level (CAL), and Gingival Index Simplified (GI-S). **Statistical Analysis:** Statistics was performed using the ANOVA test, *post hoc* test, and Pearson correlation test to compare the psychological parameter of stress with periodontal parameters among six groups of students. $P < 0.05$ was considered to be statistically significant. **Results:** Group I showed higher mean stress scores (10.78 ± 0.76) compared to other groups. The mean OHI-S (1.61 ± 0.15), mean CAL (3.68 ± 0.79), and mean GI-S (1.43 ± 0.15) scores also increased with elevated stress levels among medical students. Followed by Group VI and Group II showed almost similar results. **Conclusion:** The present study showed strong association between stress and periodontal disease and have an adverse effect over oral hygiene factors among the students.

Keywords: Depression, Anxiety, Stress scale, oral hygiene status, periodontitis, stress

Periodontitis is defined as an inflammatory disease of supporting tissues of teeth caused by specific microorganisms or groups of specific microorganisms, resulting in progressive destruction of the periodontal ligament and alveolar bone with periodontal pocket formation, gingival recession, or both.^[1]

College students often experience stress due to various reasons, of which educational demands also play a role.^[2] Stress is subjective and relative; something that may be stressful for one person may not be stressful for another.^[3] It is a state of physiological or psychological strain caused by adverse stimuli, physical, mental, or emotional, internal

or external, that tend to disturb an organism's functioning and which the organism naturally desires to avoid.^[4] The stress which is experienced by students may adversely affect their academic achievement, personal well-being, and long-term professional capabilities. Furthermore, acceleration of mental distress takes place, and it can have a negative impact on their cognitive functioning and learning.^[5]

In response to various stressful stimuli, a sequence of events is initiated. This stress can result in the deregulation

of the immune system, leading to periodontitis by two mechanisms stated by Genco are based on physiological response mediated by the HPA axis (Hypothalamo-Pituitary Axis), sympathetic-adrenal medullary axis, and others by the person's psychological behavior. An increased concentration of corticotropin-releasing hormone from the hypothalamus occurs following the HPA axis activation due to stress that in turn, acts on the adrenal cortex releases cortisol into the circulation, which produces a multitude of effects throughout the body. The second major pathway to be activated is the sympathetic nervous system, which releases catecholamines results in the adrenal medulla's activation for the secretion of norepinephrine and epinephrine, which results in a range of effects that may act to modulate immune responses, which shows flight or fight response to potentially harmful stimuli.^[4]

Stress impairs the balance between pro-inflammatory and anti-inflammatory responses. Alterations in the levels of Gingival Crevicular Fluid, interleukin-1, interleukin-6 were mediated between stress and periodontal diseases which causes reduction in polymorphonuclear leukocyte chemotaxis, phagocytosis, reduced proliferation of lymphocytes.^[6] Acute necrotizing ulcerative gingivitis, aggressive periodontitis, and latent herpes virus infection are the three conditions associated with periodontium that is severely affected by stress.^[7]

Due to the various factors such as tight academic schedule, competition among the students who are designated as different professional students and they also suffer from the burden of achieving various targets between them contributing to psychological stress development. This excessive stress, in turn, increases the prevalence of psychological factors such as depression, anxiety. Literature suggests that psychological stress has a detrimental effect on oral health.^[8] Hence, the Depression, Anxiety, and Stress Scale was designed to fill the gap in detecting common mental disorders.^[9] One practical benefit of the Depression, Anxiety, Stress Scale-21 (DASS-21) is that it was designed as a single instrument to measure symptoms of depression, anxiety, and stress given by Lovibond and Lovibond.^[10,11] Hence, this study was aimed to evaluate the association between stress and periodontitis in different professional college students.

SUBJECTS AND METHODS

This study was approved by the Institutional Ethical Committee. The present study was conducted on 360 professional college students and the sample size was calculated using an effect size of 0.25 (small), alpha error-5%; power-95%; the number of groups-6. These 360 students were classified into six groups,

each group consisting of 60 students. These students were taken from 6 different colleges in and around Guntur. The six groups included were Group 1-Medical, Group 2-Dental, Group 3-Pharmacy, Group 4-Nursing, Group 5-Engineering, Group 6-Chartered Accountancy.

The primary objective of this study remains to be evaluation of stress and its association with periodontal disease among students in professional colleges, the choice of study subjects from different academic disciplines was made to develop a preliminary insight into potential differences in stress, which is the exposure variable in this study, between academic groups and also its differential association with periodontal disease should there be any.

Criteria for selection of students

Students who were systemically healthy and pursuing their final year in the age group of between 20 and 30 years were included in this study. Students who received periodontal treatment in the last 6 months, had a habit of smoking and alcohol consumption, who used any medication (antibiotics, anxiolytics, anti-depressants) in the previous 6 months were excluded from the study.

Questionnaire

The DASS is the only self-report scale that measures all three negative emotional states, i.e. Depression, Anxiety, and Stress altogether. It is designed to maximize discrimination between the three components it measures. In clinical and community samples, DAS scale had shown high reliability that is compatible with allocating the items to subscales, exhibiting high validity with other measures of anxiety and depression. In the present study, we have used stress questionnaire in DASS-21, a short form of the DASS-42, and had many advantages over the full-length version, which includes it takes less time to complete, more consistent, the questions retained from the original version are generally superior to those excluded.^[12]

Each component of the DAS scales contains seven items. So, only seven questions that were related to stress were selected. It also estimates difficulty relaxing, nervous arousal, and being easily agitated, irritable, and impatient. When completing the DASS-21, the respondent is required to present a symptom over the previous week. Each question has four specified alternative answers giving scores ranging from 0 to 3: Score 0-“never applied to me,” score 1 - “sometimes applied to me,” score 2 - “often applied to me,” and score 3 - “applied almost always to me.” Higher scores indicate greater stress levels in individuals.

Periodontal parameters

Along with the questionnaire, periodontal parameters like Oral hygiene index - simplified (OHI-S), clinical attachment level (CAL), GI-S were also assessed.

Procedure

A questionnaire was given to all the students included in the study, followed by clinical examination, wherein OHI-S, CAL, GI-S were assessed. The questionnaire duly filled by the participants should be given to the investigator in return once the clinical examination was completed.

Referral cards were issued to all the participating students who were found to have periodontitis to avail of oral health care at the corresponding teaching dental institutions.

Statistical analysis

Data were collected and entered into an MS Excel sheet, and results were analyzed using SPSS version software. Statistical analysis was performed using One-way ANOVA and Tukey's *post hoc* test with a value of $P < 0.05$ was considered to be statistically significant. One-way ANOVA test is used to test the differences in mean scores of DAS scale, OHI-S, CAL, GI-S between the groups. Tukey's Post-hoc test is a single-step multiple comparison test. It is used to find means that are significantly different from each other. Pearson's correlation test was performed to measure the linear correlation between two variables and has a value between +1 and -1.

RESULTS

The total number of participants who were subjected to analysis was 360. Data were collected from 6 academic streams, namely, Medical, Dental, Pharmacy, Nursing, Engineering, and Chartered Accountancy. The students who responded to the questionnaire were currently in their final year undergraduate with no gender discrimination. All the clinical parameters (OHI-S, CAL, GI-S) were evaluated with each group. The obtained data were subjected to appropriate statistical analysis, and results are discussed. The differences in the study parameters between the groups are shown in Table 1

Significant differences were observed between the study groups concerning mean stress, OHI-S, CAL, and GI-S scores ($P \leq 0.05$). As significant differences between groups were found for stress, OHI-S, CAL, and GI-S, Tukey's *post hoc* tests were done.

Stress

The mean score of stress is found to be highest in Group 1 (10.78 ± 0.76), followed by Group 6 (8.6 ± 0.49); Group 2 (8.4 ± 0.49), and the least score was found in Group 4 (3.35 ± 1.84). According to the interpretation values by Lovibond and Lovibond,^[10,11] it was found that the medical students fall under the category of having a moderate level of stress and that of dental and Accountancy group students fall under the category of

Table 1: Differences in the study parameters between groups

Parameter	Group	n	Mean±SD	F	P
Stress	1	60	10.78±0.76	291.75	0.001*

having mild stress. Other groups of academic students show normal stress [Table 1 and Figure 1].

OHI-S: The mean score of OHI-S is found to be highest in Group 1 (1.61 ± 0.15), followed by Group 6 (0.77 ± 0.23); group 2 (0.58 ± 0.06), and the least score was found in Group 5 (0.25 ± 0.17). Using interpretation values given by Green and Vermillion for OHI-S,^[13] medical students showed fair oral hygiene scores while other groups showed good oral hygiene status in terms of debris and calculus deposits on teeth [Table 1].

Clinical attachment level

The mean score of CAL is found to be highest in Group 1 (3.68 ± 0.79), followed by Group 6 (3.3 ± 0.47); Group 2 (3.1 ± 0.7) and the least score was found in group 5 (0.6 ± 0.46). Using CAL scores,^[14] Medical, Accountancy, and Dental students show stage II periodontitis, whereas other groups show no signs of periodontitis [Table 1].

GI-S: The mean score of GI-S is found to be highest in Group 1 (1.43 ± 0.15), followed by Group 6 (0.6 ± 0.15); Group 2 (0.55 ± 0.15), and the least score was found in group 5 (0.27 ± 0.18). In terms of GI-S scores,

using interpretation values given by Loe,^[15] moderate gingivitis was observed in medical students. In contrast, other groups showed mild gingivitis status of gingival conditions [Table 1].

The correlation and association between clinical parameters were shown in Table 2 by performing Pearson's correlation test. The correlation between stress and OHI-S showed a 0.86, and that of stress and CAL was found to be 0.92, with GI-S, 0.84 was observed. The correlation between OHI-S, and CAL, GI-S was found to be 0.77, 0.95, respectively, and that of CAL and GI-S was 0.77. All the scores showed a statistically significant strong correlation with a $P \leq 0.05$.

The scattered plot in Figure 2 shows the correlation between stress and OHI-S with $R^2=0.743$, indicating that 74.3% of the variance in OHI-S was predicted by stress. Figure 3 shows the scattered plot representing the correlation between stress and CAL with $R^2=0.847$, indicating that only 84.7% of CAL variance was predicted by stress.

DISCUSSION

Periodontitis is a chronic inflammatory disease in the periodontal tissue mediated by the host-associated plaque biofilms, leading to progressive destruction of tooth-supporting structures and loss of periodontal attachment. The bacteria present in the subgingival microbiota results in upregulated host immune-inflammatory response in the periodontal tissues characterized by increased production of inflammatory cytokines like interleukin, tumor necrosis factor-alpha, prostanoids like PGE2 and enzymes including MMP's. These upregulated pro-inflammatory mediators are responsible for majority of periodontal tissue breakdown that occurs including

alveolar bone resorption by the activation of osteoclasts. These changes result in the development of clinical signs of periodontal disease. The pathogenesis of the periodontal disease is modified mainly by local factors such as the

presence of plaque and calculus, systemic diseases, and also environmental factors such as smoking and by genetic susceptibility.^[1]

In the present study, the relationship between stress and periodontal disease has been evaluated using the DAS scale's stress component. The results of our study suggest that the psychological property of stress in DAS scale is more related to group 1 (Medical students) when compared to other groups and these results are in accordance with a study conducted by Moayedi *et al.*, where they evaluated stress levels among medical, dental, pharmacy, and nursing students.^[16]

Our study is following other studies conducted by Behere *et al.*, where nursing students were least stressed compared to medical and engineering students;^[17] Mayildurai *et al.* evaluated the stress among only engineering students and stated that they are distressed in a significant level.^[18] Hou *et al.* stated that stress among accounting students might be due to 5 factors such as assistance, assessment, assignment, course difficulty, and presentation and career.^[19] Nor *et al.* stated that 92.4% of accountancy students experience stress.^[20] A study conducted by Kamble and Minchekar showed a positive correlation observed between stress and depression among college students.^[21]

Study conducted by Murphy *et al.* showed that dental students experience more stress than medical students except in professional identity.^[22] Taneja *et al.* stated that emotional distress is common among medical students.^[23] Among dental students, clinical year students were more stressful than nonclinical year students was stated by Sravani *et al.*^[12] Singh and Singh stated that professional students are more stressful than nonprofessional students.^[24] Noureen *et al.* showed that stress in nursing students might be due to anxiety, fear of handling patient, solicitude, fear of distinction by teachers and staff.^[25]

It has been stated that stress negatively influences oral health status.^[26,27] The present study revealed that OHIS, CAL, and GIS values were higher among medical students than in other groups. This increase in periodontal parameters was observed with increasing stress values. An increase in OHIS, CAL, GIS values was also evident, indicating that the students have poor oral hygiene practice under stressful conditions. A few studies suggest that students generally neglect their oral health care under conditions of stress, thereby showing poor oral status leading to periodontitis.^[28,29] These findings are in coincidence with the findings of our study. Similarly, another study conducted by Mahmood *et al.* suggested that there is strong evidence of an association between examination stress and periodontal parameters.^[30]

The present study evaluated the relationship between stress and periodontitis by observing the correlation of stress with periodontal parameters, which was strong. In this study, even though there is an increased level of awareness of oral hygiene practices among dental students compared to other students, there was no difference in the periodontal parameters between them.

The role of potential confounders such as oral hygiene practices and deleterious habits cannot be ignored while attempting to ascertain such direct association. However, it can be hypothesized that oral hygiene practices and acquisition of deleterious habits can be directly influenced by the stress levels of the subjects and these factors have a mediating role to play in the association between stress and periodontitis.

Certain limitations of the present study include no clear demarcation on the type of stress that the student is facing. A self-reported questionnaire that the responders may or may not reveal their true experience of stress, heterogeneous sex distribution.

CONCLUSION

Of the six groups, medical students had shown higher values of both stress and periodontal parameters than other groups. The accountancy group and dental group showed almost similar results regarding stress and the evaluated clinical parameters. Therefore, it was concluded that psychological factors have an adverse effect on the student's oral hygiene factors. The worsening of periodontal parameters could be due to the student's negligence because of stressful conditions. Hence, education of students regarding the relationship between the stress-periodontal disease (oral hygiene), thereby avoiding the stress-induced factor behind the negligence of oral hygiene.

Perceptions and Preparedness of Dental Professionals toward COVID-19-Related Oral Manifestations in India

Ramanarayana Boyapati, Hema Duddukuri¹, Ravindranath Dhulipalla, Lakshmikanth Kolaparthi, Tejaswin Polepalle, Kishore Kumar Katari

Department of Periodontics, Sibar Institute of Dental Sciences, Takkellapadu, Guntur, Andhra Pradesh, ¹Department of Periodontics, Mamata Dental College, Khammam, Telangana, India

Abstract

Background: With the reports of oral manifestations observed in coronavirus disease 2019 (COVID-19) patients snowballing day-by-day, it calls for the attention of dental professionals to keep themselves updated regarding these manifestations and how to prevent and manage them in COVID-infected patients. **Aims and Objectives:** The aim of this study is to assess the perceptions and preparedness of dental professionals in India toward the COVID-19-related oral manifestations. **Materials and Methods:** A cross-sectional, web-based survey was conducted on dental professionals using a pretested and validated questionnaire. Six hundred and twenty-three responses obtained from January 23, 2021 to February 15, 2021 were included in the study. **Results:** Mean knowledge scores regarding COVID-19-related oral manifestations were noted to be significantly high among males (13.5 ± 4.9), having a PhD (18.3 ± 5.8), belonging to the specialty of oral medicine and radiology (15.6 ± 4.7), with more than 15 years of clinical experience (15.4 ± 4.7) and practicing in metropolitan areas (13.7 ± 5.03). Tele-consultation and advising palliative care (65.5%) were the most preferred ways of managing COVID-19-related oral manifestations. Ninety-one percentage of the participants felt that inclusion of dentists in the intensive care unit multiprofessional teams, would contribute toward early diagnosis and management of oral manifestations. **Conclusion:** Study noted lower knowledge scores pertaining to COVID-19-related oral manifestations among BDS graduates with <5 years of clinical experience calling for the implementation of continuing dental education on the oral manifestations occurring in COVID-19 patients.

INTRODUCTION

As the pandemic hit the world, it immensely shook everyone's lives affecting almost every sector including and mainly healthcare. Oblivious to what has befallen, researchers across the world delved into the whys and wherefores of the pandemic. Intriguingly, the research published in recent times disclosed the occurrence of oral manifestations in coronavirus disease 2019 (COVID-19)-infected patients. Chaux-Bodard *et al.*^[1] has first published a case of tongue ulceration noticed in a 45-year-old COVID patient. Zarch and Hosseinzadeh^[2] found dry mouth as a common oral manifestation of COVID-19 followed by dysgeusia and candidiasis after reviewing 170 cases in 17 studies. Favia *et al.*^[3] has categorized the oral lesions seen in COVID-19 patients into four groups based on features of the lesions, timing of their occurrence, and the treatments administered: (a) Probably, preexisting conditions (b) severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2)-related lesions

(c) Treatment-related lesions (d) Lesions related to poor oral hygiene.

The possible mechanisms for the occurrence of these oral manifestations in COVID patients are still ambiguous. Nonetheless, the oral cavity could be a potential target organ of SARS-CoV-2 owing to the expression of angiotensin-converting enzyme 2 and furin in oral tissues, which play a pivotal role in SARS-CoV-2 invasion of host cells.^[4] Hence, it is essential for oral health care providers to be aware of how COVID-19 and its treatments affect oral health. In this context, the present study

aimed to assess the perceptions and preparedness of dental professionals toward COVID-19-related oral manifestations.

MATERIALS AND METHODS

Study design and population

A cross-sectional web-based study was conducted using an online questionnaire to assess the perceptions of dental professionals including dentists, postgraduates, and interns in India regarding the oral manifestations reported among COVID-19 patients and their preparedness to prevent and manage them. The dental professionals who were involved in patient care during the COVID pandemic were included in the study. The study was carried out from January 23, 2021 to February 15, 2021.

Questionnaire development and pretesting

Following an electronic search of the databases for the literature published on the impact of COVID-19 and its treatment on the oral cavity and the oral manifestations that were reported in COVID-19 patients, a preliminary questionnaire was constructed under three sections:

- Demographic data
- Perceptions toward COVID-19-related oral manifestations
- Preparedness toward COVID-19-related oral manifestations.

The questionnaire was reviewed for clarity, face, and content validity by a panel of experts, followed by pilot testing on participants. It was further evaluated for internal consistency reliability (Cronbach's alpha – 0.82) and test-retest reliability among 40 participants (Intraclass correlation coefficients – 0.92). The questionnaire contained 5 knowledge-related questions with multiple correct responses and a score of 1 was given for each correct response, which accounted to a maximum possible knowledge score of 29.

Sample size

Sample size was calculated using G*Power 3.1.9.2 software (University of Dusseldorf, Germany). Based on the observations by Arora *et al.*^[5] on the knowledge and preparedness of Indian dentists during COVID-19 pandemic, a sample size of 400 was deemed sufficient at an alpha level of 5% and power of 80%. The formula used for sample size calculations was $Z\alpha 2pq/d^2$.

Data collection

The revised questionnaire prepared using Google forms was shared through E-mail and Whatsapp to the dental health care professionals through convenience and snowball sampling. Participants were informed that their participation in the study will be anonymous and will be considered their consent to participate and publish the data provided by them. In fulfillment of the key considerations proposed by Wicher and Wu^[6] for determining the need for an ethics oversight for survey research, the present study excluded participants who are vulnerable or with diminished autonomy, and there was no greater than minimal informational or psychological

harms present to the participants. Hence an ethical clearance was deemed not to be necessary from an Institutional Review Board. A total of 623 responses obtained during the study period were included in the study.

Statistical analysis

The data were compiled into Microsoft excel sheet and subjected to statistical analysis using the Statistical Package for the Social Sciences-20.0 (IBM SPSS, Armonk, NY, USA). The statistical tests used to analyze the data were Chi-square test, Kruskal–Wallis ANOVA, and Mann–Whitney *U*-test.

RESULTS

Background characteristics of the participants

Among the 623 dental professionals who had participated in this study, 342 (54.9%) were females. The mean age of the participants was 32.03 ± 10.83 years. Slightly more than half of the study participants were working in urban areas (51.7%) and only 18.6% had clinical experience of more than 15 years [Table 1].

Participants' perceptions toward coronavirus disease 2019-related oral manifestations

Nearly, half of the respondents (46.1%) had either screened or treated COVID-19 infected or recovered patients for oral health problems. However, only 17.3% of the study participants reported coming across COVID-19 diagnosed or recovered patients presenting with oral manifestations. Among the participants, males and those having a PhD with more than 15 years of clinical experience belonging to the specialties oral surgery and orthodontics reported significantly ($P < 0.05$) higher experience in treating or screening for oral health problems and noticing oral manifestations in COVID-19 patients [Table 1]. Osteomyelitis, ulcerations, and candidiasis were the most reported oral manifestations that were noticed by the study participants in COVID-19 patients [Table 2]. Nearly, 80% held the notion that oral tissues are one of the target organs in COVID-19 infection, and agreed that COVID-19-infected patients might present oral manifestations along with systemic features. Less than 40% of the study participants were aware of the term “*COVID tongue*.”

Participants' knowledge toward coronavirus disease 2019-related oral manifestations

Among the COVID-19-related oral manifestations reported in the published literature, alteration or loss of taste sensation (66%), ulcerations and blisters (59.6%), and opportunistic infections (58.4%) were the most known manifestations to the participants, whereas, melanin hyperpigmentation (4.8%), fixed drug eruptions (8%), and petechiae (8.2%) were the least known. About 80% of the participants believed that COVID-19-infected patients with underlying systemic diseases were most susceptible to develop oral manifestations. About 76.7% opined that the oral manifestations develop secondary to deterioration of systemic health in COVID affected patients and opted underlying

systemic diseases (69.3%) and poor oral hygiene (61.2%) as the predisposing factors. About 80.3% chose steroids and 52.3% chose antivirals as the drugs used for COVID-19 treatment which are more likely to cause COVID-19-related oral manifestations when used for longer duration [Table 3].

Upon comparison of background characteristics, male oral health care professionals (13.5 ± 4.9), having a PhD (18.3 ± 5.8), belonging to the specialty of oral medicine and radiology (15.6 ± 4.7), with more than 15 years of clinical

experience (15.4 ± 4.7), and practicing in metropolitan areas (13.7 ± 5.03) demonstrated significantly higher mean knowledge scores ($P < 0.05$) [Table 4].

Specialists in oral and maxillofacial surgery, oral medicine, and radiology showed significantly higher mean scores compared to those with no specialization after adjusting for variables such as gender, highest level of education, years of clinical experience, and location of work. Similarly, study participants with more than 10 years of clinical experience had higher mean

COVID-19: Coronavirus disease 2019, HSV: Herpes simplex virus

knowledge scores compared to those with <5 years of clinical experience [Table 5].

Preparedness of the participants toward coronavirus disease 2019-related oral manifestations

Teleconsultation and advising palliative care based on the oral manifestations present (65.5%) was found to be the most preferred way of managing oral manifestations in COVID-19 patients by the study participants. More than 92% of oral health care professionals participated in this study opined that dental check-ups are necessary for COVID-19 affected participants on long-term steroid therapy in light of their vulnerability for opportunistic infections. Eighty-seven percentage agreed that COVID-19 patients on

long-term steroid therapy with preexisting systemic diseases require prophylactic antibiotics and antifungals to prevent the emergence of secondary infections. Furthermore, 91% held the notion that inclusion of dentists in the intensive care unit (ICU) multiprofessional teams would contribute toward early diagnosis and management of oral manifestations in COVID-19 patients.

DISCUSSION

The novel coronavirus disease was found to impact oral health with about 45% of the COVID-19-infected patients presenting with oral manifestations.^[7] In the present study, almost 80% of the participants agreed that COVID-19 patients

might present oral manifestations and believed that oral tissues are one of the target organs in COVID-19 infection. Less

than 20% of the study participants reported coming across COVID-19 diagnosed or recovered participants presenting with oral manifestations. This could be due to missed diagnosis and reporting of the cases rather than less incidence of the cases alone. The mean knowledge scores concerning COVID-19-related oral manifestations was relatively high among participants having a PhD, with more than 10 years of clinical experience compared to BDS graduates with clinical experience of <5 years which could be attributed to their limited exposure to the current research data regarding the disease processes and manifestations.

Our study found that among the various COVID-19-related oral manifestations, alteration or loss of taste sensation (66%), ulcerations and blisters (59.6%), and opportunistic infections (58.4%) were known to the majority of the participants. This is in accordance with the occurrence of the findings reported by Santos *et al.*,^[8] where they stated gustatory disorders as most commonly noticed manifestations followed by oral mucosal lesions.

More than half of the participants believed that the occurrence of COVID-19-related oral manifestations is secondary to deterioration of systemic health and due to treatments used for COVID-19, mostly due to long-term usage of steroids and anti-virals. Brandini *et al.*^[9] suggested possible etiologies for the occurrence of these oral lesions:

- Direct or indirect interaction of SARS-CoV-2 with oral cells resulting in disruption of tissue integrity,
- Adverse reactions of the drugs used for COVID treatment triggering lesions of herpes simplex virus, candida, xerostomia, nonspecific ulcerations, and gingivitis and
- Hyperinflammatory, as well as immunosuppressive conditions induced due to COVID infection might cause viral reactivation and promote the growth of opportunistic organisms.

More than half of the study participants believed underlying systemic diseases, poor oral hygiene, hyperinflammatory response secondary to COVID-19 infection, and stress as the predisposing factors for the oral manifestations seen in COVID patients. On similar note, Fidan *et al.*^[10] supposed that these lesions were a consequence of various factors including poor oral hygiene, stress, and systemic infections. Viral invasion and dysbiosis induced by the use of therapeutic drugs might also be involved in the occurrence of oral lesions in COVID-19 patients.^[11] Among the various drugs used for the treatment of COVID-19, when used for longer duration, steroids were known to cause opportunistic infections and anti-virals can lead to dry mouth, taste disturbances, ulcerations, erythema multiforme, and parotid lipomatosis.^[12,13]

The infectious nature of this novel disease makes it challenging to adhere with the routine oral disease diagnosing and managing strategies. The study participants preferred the use of teleconsultation and advice palliative care based on the oral manifestations present. Guo *et al.*^[14] proposed that acute oral mucosal lesions treatments were based on the type of the lesion

seen and advised the use of systemic antibacterials, antivirals, antihistamines, immunosuppressants, and low-to-medium doses of glucocorticoids as required with topical adjuncts such as anti-inflammatory gargle and ointment, chlorhexidine and povidone-iodine solution, and topical glucocorticoid preparations, to ease the pain and promote healing of lesions. They also advised the use of web-based consultations and lesion photographs to aid in the diagnosis of oral-mucosal lesions, especially for patients with active COVID infection.

The majority of participants as preventive strategies, reckoned that dental check-ups are necessary for COVID-19 patients who were on long-term steroid therapy and believed that these patients might require prophylactic antibiotics and antifungals to prevent the emergence of secondary infections, especially those with systemic comorbidities. Santos *et al.*^[15] stated that dental follow-ups are necessary for the COVID patients following dismissal from the hospital. They also highlighted the role of dentists in maintaining the oral health of the ICU-admitted COVID-19 affected patients. In agreement with this, 91% of the participants deemed that inclusion of dentists in the ICU multiprofessional teams would contribute toward early diagnosis and management of oral manifestations in COVID-19 patients.

CONCLUSION

The myriad of oral manifestations occurring in COVID patients appears to be multifactorial in origin with varying severity. Although the majority of the reported cases are not fatal, certain conditions such as osteomyelitis and necrotic diseases can wreak havoc, if left untreated and needs to be diagnosed at the earliest. Dental professionals should scrutinize for the presence of oral lesions while treating patients who were infected and treated for COVID-19 to provide oral care and improve patient's quality of life. It is also imperative to develop guidelines for diagnosing and managing the COVID-19-related oral manifestations.

Effect of nonsurgical periodontal therapy and smoking status on hematological variables related to anemia of chronic disease in chronic periodontitis patient: a case-control study

Sangita Show¹, Somen Bagchi², Arka Kanti Dey³, Ramanarayana Boyapati⁴, Pritish Chandra Pal⁵, Kanikanti Siva Tejaswi⁴

⁵Department of Periodontology, Pacific Dental College and Hospital, Udaipur, India

Background: Chronic infectious, inflammatory, or neoplastic disorders are associated with anemia of chronic disease. Chronic inflammatory diseases such as periodontitis may contribute to masked anemia, especially in smokers. This study was aimed at verifying and comparing the efficacy of nonsurgical periodontal therapy (NSPT) for improving anemia among chronic periodontitis patients with and without the habit of smoking.

Methods: Thirty systemically healthy individuals with chronic periodontitis were divided into two groups of 15 each, smokers (group A) and nonsmokers (group B). The groups were compared based on hematological parameters such as serum erythropoietin (SE) and serum ferritin (SF) levels at baseline and 3 months after NSPT for anemia evaluation.

Results: The baseline SE levels in groups A and B were 11.84 and 15.19 mIU/mL ($p=0.031$), respectively; the corresponding levels at 3 months after NSPT were 13.00 and 17.74 mIU/mL ($p=0.022$). The baseline SF levels in groups A and B were 95.49 and 44.86 ng/mL ($p=0.018$), respectively; the corresponding levels at 3 months after NSPT were 77.06 and 39.05 ng/mL ($p=0.009$). Group B showed a significant increase and decrease in the SE and SF levels, respectively, at 3 months after NSPT ($p=0.035$ and $p=0.039$, respectively), whereas group A showed insignificant changes ($p=0.253$ and $p=0.618$, respectively).

Conclusion: NSPT led to an improvement in anemia among chronic periodontitis patients. However, the improvement is less in smokers compared to that in nonsmokers. Furthermore, SF and SE levels might serve as effective biomarkers for assessing anemia in smokers and nonsmokers with chronic periodontitis.

Introduction

Chronic infectious, inflammatory, or neoplastic disorders are associated with anemia of chronic disease (ACD) [1]. Pathophysiological factors such as limited iron availability to erythroid progenitor cells, a blunted response to erythropoietin, erythrophagocytosis, diminished erythropoiesis, and microbial/tumor cell infiltration of bone marrow contribute to the development of ACDs. Patients with ACD demonstrate diminished levels of serum iron, normal to elevated serum ferritin (SF) levels, and normocytic to microcytic anemia [2]. Periodontitis is a chronic inflammatory disease characterized by increased production of inflammatory cytokines that can contribute to the prevalence of anemia by directly inhibiting erythropoiesis and inducing changes in iron absorption and release [3].

Patients with chronic periodontitis (CP) who are regular smokers show lower gingival redness and bleeding on probing due to potential vasoconstriction caused by the nicotine content in tobacco. This may lead to an inaccurate assessment of periodontal status and failure to diagnose the underlying pathogenic state [4]. In addition, smoking causes an increase in hemoglobin (Hb) concentration mediated by carbon monoxide, which bonds with Hb and forms inactive carboxyhemoglobin (COHb) with a reduced ability to deliver oxygen to the tissues. Therefore, as a compensatory mechanism, smokers maintain a higher Hb level than nonsmokers, which is referred to as secondary polycythemia [5,6]. Despite the higher Hb levels found in smokers, this hypoxic state triggers erythropoietin production, thereby increasing erythropoiesis. Erythropoietin is a large glycoprotein hormone produced by the peritubular cells lining the kidneys and hepatocytes; it is the principal regulator of the erythrocyte lineage [7]. This clearly implies that the underlying anemic state in smokers is masked by high Hb values, which may lead to an underestimation of the prevalence of anemia among smokers [8]. In such a scenario, an estimation of serum erythropoietin (SE) levels may aid in assessing the anemia status of smokers.

In chronic inflammatory conditions such as CP, proinflammatory cytokines such as interleukin (IL)-1 α , IL-1 β , IL-6, tumor necrosis factor- α , and transforming growth factor- β not only increase hemolysis and impair erythropoiesis via direct bone marrow suppressive effects but also release reactive oxygen species that inhibit erythropoietin gene expression [9]. Singh et al. [10] and Hutter et al. [11] found lower erythropoietin levels in patients with CP, thereby strengthening the hypothesis that CP may lead to ACD.

Acute-phase proteins are biomarkers that show changes in plasma concentration that increase (positive acute-phase proteins), such as ferritin, or decrease (negative acute-phase proteins) by at

least 25% during inflammatory disorders, due to their altered production by hepatocytes [12]. Ferritin serves as the main iron storage protein in the body and contains 20% iron by weight. The serum iron concentration is directly proportional to its storage in the body, which increases under inflammatory conditions and iron overload. Chakraborty et al. [13] observed that SF levels were higher in patients with CP than in healthy controls, and a reduction was noted with remission of chronic inflammation following nonsurgical periodontal therapy (NSPT). Considering the prevalence of periodontal disease in the community at large, its deleterious effects on the systemic health of affected individuals, the increased use of tobacco in the form of cigarette smoking, and the resultant masking of anemia status, therapeutic measures such as scaling and root planning (both NSPTs) might significantly improve anemia status in such individuals.

The available literature suggests that NSPTs were not tested while evaluating erythropoietin levels in smokers and nonsmokers with CP. To date, only a few studies have evaluated NSPTs with a single hematological parameter to assess ACD in CP cases. Hence, multiple hematological parameters, such as SF and SE levels, collectively might serve as a better means to assess the anemia status of smokers with CP instead of any single parameter. The aim of the present study was to verify and compare the efficacy of NSPT in improving anemia status among patients with CP who do or do not smoke.

Methods

Ethical statements: This study was carried out following CONSORT (Consolidated Standards of Reporting Trials) guidelines and written informed consent was obtained from all participants who fulfilled the inclusion criteria and agreed to participate voluntarily. Details about the nature, risk, and benefits of the hematological investigations as well as the associated procedures were explained to all participants. The experimental protocol and consent form were approved by the Institutional Ethical Committee and Institutional Review Board (IRB) of Dr. R. Ahmed Dental College and Hospital (IRB No: DCH/07/18-19).

1. Study design

This clinico-biochemical study included 30 systemically healthy patients diagnosed with CP stage I/II (probing pocket depth of ≥ 4 mm but < 6 mm) requiring NSPT who were selected from the outpatient Department of Periodontics [14]. CP was confirmed clinically and radiographically according to the guidelines of the

2017 Periodontology Consensus Report [14]. Subjects were divided into two groups ($n = 15$ per group) based on their smoking history. Group A included current smokers (i.e., individuals with a history of smoking ≥ 100 cigarettes in their lifetime and currently smoking) and group B included never smokers (i.e., individuals who never smoked/history of smoking < 100 cigarettes in their lifetime) [15]. Pregnant and lactating mothers, former smokers, and those with any history of systemic illness, history of iron supplements or blood loss, any periodontal surgery in the last 6 months, and pocket depth ≥ 6 mm were excluded from the study.

After careful periodontal examination and diagnosis, venous blood samples were obtained in the early morning to avoid diurnal variations in SE levels. Peripheral venous blood (4 mL) was obtained by venipuncture (Mokshy Surgicals Ltd., Mumbai, India) in the antecubital fossa from each participant selected for hematological tests. The blood was transferred to non-vacuum clot activator (coated with micronized silica) blood collection tubes. The collected blood samples were kept at room temperature for approximately 2 hours to allow the blood to clot, and serum was obtained after centrifugation for 10 minutes at 2,500 revolutions per minute (Remi Elektrotechnik Ltd., Thane, India). The serum was then assayed for baseline periodontal and hematological parameters (SF and SE). The selected subjects in both groups then received NSPT, including ultrasonic scaling, root planing, and polishing, as required. Thorough oral hygiene instructions and demonstration of proper brushing technique were provided. The patients were asked to return at 1- and 3-month intervals for follow-up, and additional oral prophylaxis was administered at those times if required. All periodontal interventions were performed by an expert periodontist who was unaware of the specific grouping of the subjects. The final hematological data were recorded at the 3-month follow-up, and statistical analysis of the data was carried out. Oral hygiene was maintained at an optimal level during the study period.

SF levels were measured using an Access Immunoassay System and analyzed using an automated analyzer (Beckman Coulter Immunoassay System, Brea, CA, USA). SE levels were assessed using an enzyme-linked immunosorbent assay (ELISA) kit for erythropoietin and an Adonis ELISA plate reader system (Triveni Traders & Diagnostic Private Ltd., Thane, India).

2. Statistical analysis

The Shapiro-Wilk test was performed to assess the assumption of normality of the data. Data are presented as mean \pm standard error of the mean (SEM). An unpaired Student *t*-test was performed to compare the parameters of the two groups that showed normal distributions. Normally distributed paired data of each group were

compared using a paired Student *t*-test. Non-normally distributed unpaired data were evaluated using the Mann-Whitney *U*-test, and paired data were evaluated using the Wilcoxon matched-pairs signed-rank test. Correlations between two normally distributed parameters were evaluated using the Pearson correlation test. Sex distribution between the two groups was evaluated using Fisher exact test. The correlation between two non-normally distributed parameters was evaluated using Spearman nonparametric correlation. Direct and inverse correlations were indicated by positive and negative correlation coefficient (*r*) values, respectively. An absolute value of *r* of 1.0 to 0.5, 0.5 to 0.3, 0.3 to 0.1, and < 0.1 was considered strong, moderate, weak, and no correlation, respectively. Differences were considered statistically significant at $p < 0.05$. Statistical analysis was performed using Graph Pad Prism ver. 5, 2007 (Graph Pad Software Inc., San Diego, CA, USA).

Results

The Shapiro-Wilk test and visual inspection of the histograms and quantile-quantile plots suggested that the collected data were normally distributed. In the present study, the ages (mean \pm SEM) of the participants in groups A and B were 47.73 ± 2.33 years and 41.93 ± 2.79 years, respectively. An unpaired Student *t*-test showed that the mean age of the participants was not statistically different between the groups ($p = 0.122$) (Table 1). Regarding sex distribution between the groups, group A had nine male patients and six female patients, and group B had seven male patients and eight female patients. A chi-square test showed that there was no statistically significant difference in the sex distribution ($p = 0.457$). Hence, confounding variables, such as age and sex, did not affect the study results (Table 1). Group B showed higher SE levels than group A both at baseline (group A, 11.84 ± 1.24 mIU/mL and group B, 15.19 ± 0.79 mIU/mL; $p = 0.031$) as well as after 3 months of periodontal intervention (group A, 13.00 ± 1.40 mIU/mL and group B, 17.74 ± 1.36 mIU/mL; $p = 0.022$) (Table 2, Fig. 1). No significant alteration in the SE level was observed in group A

Table 1. Demographic details of the different study groups

Demographic variable	Group A	Group B	<i>p</i> -value
No. of patients	15	15	
Age (yr)	47.73 ± 2.33	41.93 ± 2.79	0.122 ^{a)}
Sex, male:female	9 (60.0):6 (40.0)	7 (46.7):8 (53.3)	0.457 ^{b)}

Values are presented as number only, mean \pm standard error of mean, or number (%).

Group A, smokers; group B, nonsmokers.

^{a)}Analyzed by independent samples *t*-test; ^{b)}analyzed by chi-square test. $p < 0.05$, statistically significant.

Table 2. Intergroup comparison of serum erythropoietin levels (mIU/mL) at baseline and at 3 months of treatment

Time	Serum erythropoietin level (mIU/mL)		<i>p</i> -value ^{a)}
	Group A (n = 15)	Group B (n = 15)	
Baseline	11.84 ± 1.24	15.19 ± 0.79	0.031
At 3 mo	13.00 ± 1.40	17.74 ± 1.36	0.022
<i>p</i> -value ^{b)}	0.253	0.035	

Values are presented as mean ± standard error of mean.

Group A, smokers; group B, nonsmokers.

p < 0.05, statistically significant.

**Fig. 1.** Evaluation of serum erythropoietin (SE) levels. Group A, smokers; group B, nonsmokers.

(*p* = 0.253) after 3 months of periodontal therapy (Table 2). However, the SE level in group B increased significantly (*p* = 0.035) after 3 months compared to the baseline level (Table 2, Fig. 1).

Considering the SF level data, group A showed statistically significant higher values of SF than group B at baseline (group A, 95.49 ± 21.53 ng/mL and group B, 44.86 ± 4.69 ng/mL; *p* = 0.018). Whereas group B showed statistically lower (group A, 77.06 ± 14.06 ng/mL and group B, 39.05 ± 5.46 ng/mL; *p* = 0.009) SF level compared to group A after 3 months of NSPT (Table 3, Fig. 2). However, no significant alteration (*p* = 0.618) in SF level was observed in group A after 3 months of treatment compared to the baseline level. However, the SF level in group B decreased significantly (*p* = 0.039) after 3 months of NSPT compared with the corresponding baseline level (Table 3, Fig. 2).

Table 3. Intergroup comparison of serum ferritin levels (ng/mL) at baseline and at 3 months of treatment

Time	Serum ferritin level (ng/mL)		<i>p</i> -value ^{a)}
	Group A (n = 15)	Group B (n = 15)

Discussion

The underlying anemia status in smokers may be masked by relatively higher Hb values, which are usually tested to assess anemia. This may lead to an underestimation of the prevalence of anemia among smokers. The available literature suggests that only a few studies have analyzed the efficacy of periodontal interventions, such as NSPT, on the anemia status of such patients by assessing SE or SF.

In the present study, the baseline mean SE levels were significantly lower (*p* = 0.031) in smokers with CP than in nonsmokers with CP. In addition, SE levels were negatively correlated with smoking at baseline. These findings are consistent with those of Tanabe et al. [16] and Eisenga et al. [17]. During daytime smoking, higher SE levels lead to erythrocytosis, which in turn inhibits

further erythropoietin production through a negative feedback loop. Endogenous circulating erythropoietin with a half-life of 6 to 8 hours would result in low SE in the morning hours when blood samples are usually drawn [17]. This phenomenon is supported by the circadian rhythm of SE levels described by Miller et al. [18]. An alternative explanation may be derived from the study by Weinberg et al. [19] who observed the JAK2 V617F mutation in cigarette smokers and suggested that the erythrocytosis observed in smokers occurs via an erythroid cell-intrinsic erythropoietin-independent mechanism. They also stated that this may be an unidentified direct effect of smoking on erythropoiesis. Chronic smoking initially induces an increase in erythrocyte volume, plasma volume, and erythropoietin concentration, the latter of which is reduced when the erythrocyte volume increases. Hence, erythropoietin production represents a balance between stimulation by hypoxia and negative feedback by increasing erythrocyte volume [14]. The release of proinflammatory cytokines from peripheral neutrophils and various parameters of inflammation in plasma seem to be affected more by cigarette smoking than periodontal disease, which might contribute to the downregulation of erythropoietin production. Elevation of these inflammatory mediators leads to inhibition of the hormone erythropoietin and erythropoiesis, leading to the development of anemia [20].

In the present study, 3 months following the NSPT intervention, SE levels increased from baseline values in group A, although they were not statistically significant ($p = 0.253$). In contrast, the group B patients showed a statistically significant ($p = 0.035$) improvement in SE levels following periodontal intervention. This is in agreement with the results of Miller et al. [21], who failed to detect differences in SE levels when the COHb concentration changed following smoking cessation. As a possible explanation, they mentioned that small changes in COHb were not sufficient to trigger an erythropoietin response in persons with normal lung function. In the present study, the mean SF levels at baseline were significantly higher ($p = 0.018$) in group A than in group B. Ghio et al. [22] supported this finding of increased SF levels among smokers compared with those among nonsmokers. They correlated this finding with the systemic accumulation of iron after cigarette smoke exposure and concluded that cigarette smoke alters iron homeostasis both in the lung and systemically. However, that study did not include patients with CP. Contradictory findings were obtained in a study by Erdemir et al. [23], who noted similar SF levels among smokers and nonsmokers. These findings were in agreement with those of patients with ACD, who had normal to elevated SF levels. However, the possible cause of the similar SF values in both groups was not explained in that report. A cross-sectional study conducted by Prakash et al. [24] assessed the anemia status

of nonsmoking patients with CP by evaluating various hematological parameters. No significant changes in SF levels were observed between the study groups. In the present study, the mean SF levels in group B were significantly lower ($p = 0.0397$) at 3 months after NSPT than at baseline. This is in agreement with the study of Chakraborty et al. [13], who detected relatively higher SF levels in smokers with CP than in nonsmokers with CP, and these levels were restored to normal following NSPT intervention. The mean SF levels in the present study at 3 months after NSPT were reduced in group A compared to baseline; however, the difference was not statistically significant ($p = 0.618$). The available literature does not include any comparable studies.

One limitation of the present study is its relatively small sample size. Further studies involving larger sample sizes and other parameters may be conducted in the future if required.

Overall, NSPT leads to a relative increase in SE levels and a relative decrease in SF levels, thereby indicating an improvement in the anemia status of both smokers and nonsmokers. However, the magnitude of the changes was less in smokers. Hematological parameters such as SF and SE might serve as effective biomarkers for assessing anemia status in nonsmokers with CP. For smokers with CP, further studies with larger sample sizes may clearly demonstrate the effect of NSPT on SE and SF levels among these individuals.

Posterior superior alveolar nerve block (PSANB) is one of the most common and safe injection techniques in the field of dentistry. As with any other procedure, it also has inherent complications, of which ophthalmic complications are relatively rare. Transient diplopia following the administration of PSANB is rare and daunting for both the patient and the clinician. We present a case of transient diplopia in a 26-year-old female patient following administration of PSANB and review its probable pathophysiology and management and prevention.

INTRODUCTION

Posterior superior alveolar nerve block is one of the most frequently administered injection techniques in dentistry. However, hematoma is among the most common complications of this technique, which includes mandibular nerve and V3 division anesthesia [1]. Other unusual complications attributed to drugs and procedural complications include pain on injection, edema, needle breakage, and post-anesthetic lesions, while toxicity and allergic reactions may be related to drug-body responses.

In addition to these local complications, ocular complications are also rare. To date, a very limited number of ophthalmologic complications secondary to intraoral anesthetic injections have been recorded.

Posterior superior alveolar nerve block anesthesia is, however, a common cause of ophthalmic complications after intraoral local anesthetic administration [2].

Motor/sensory complications, such as diplopia, occur due to the spread of the local anesthetic solution through the vascular, neurological, myofascial, or lymphatic networks [3]. These symptoms are generally temporary and regain normal function after the anesthetic effect is weaned off. However, such an event is distressing for both patients and clinicians. Hence, awareness of such situations is important for the management of unwarranted complications. Herein, the authors discuss one such case, in which the patient developed signs of diplopia after undergoing tooth extraction.

Fig. 1. No abduction in the left eye

CASE REPORT

A 26-year-old, otherwise healthy, woman was admitted to a private dental clinic for continuous pain in the upper left side of her jaw. Routine clinical and radiological assessments revealed chronic irreversible pulpitis with a grossly decayed maxillary left-third molar. After determining that there was no significant previous medical or dental history, extraction of the maxillary left third molar was planned. On the day of the extraction, routine preoperative vital signs were monitored and found to be normal. After obtaining consent for the tooth removal, a standard protocol was followed. Posterior superior alveolar and greater palatine nerve blocks were administered with 2% lignocaine HCl with 1:80,000 adrenaline in volumes of 1.5 ml and 0.5 ml, respectively. After confirmation of the signs and symptoms in the patient, the tooth was extracted with minimal trauma.

Just before discharge, she complained of double vision. Local measures were taken to control the hematoma. On examination, the pupils were equal, round, reactive to light, and accommodating. The patient complained of inadequate abduction in the left eye (Fig. 1). However, movement of the eye in all other directions was apparent. A clinical evaluation of the facial nerve was performed

Fig. 2. Restoration of the abductive movement in the left eye

using various methods and no abnormalities were observed.

A provisional diagnosis of transient diplopia, secondary to a posterior superior alveolar nerve block, was made based on the events leading to her clinical symptoms. The affected eyelid was taped in a closed position to provide corneal protection and to prevent further damage. Diplopia was checked every 15 min, and complete recovery was reported after 30 min. Ocular movements were reassessed to confirm restoration of the full range of movement in all gazes of the left eye (Fig. 2). The patient was kept under observation and no further complaints were noted at that time. The patient was referred to an ophthalmologist to rule out diplopia and ocular mobility. Appropriate tests were conducted to prove adequate mobility and to rule out diplopia. These were the forced duction test, Hess chart, and diplopia chart.

DISCUSSION

With myths related to loss of vision following removal of the upper teeth being very prevalent in the general public, extraction of maxillary teeth remains fearsome for a majority of patients. Despite a number of conversations

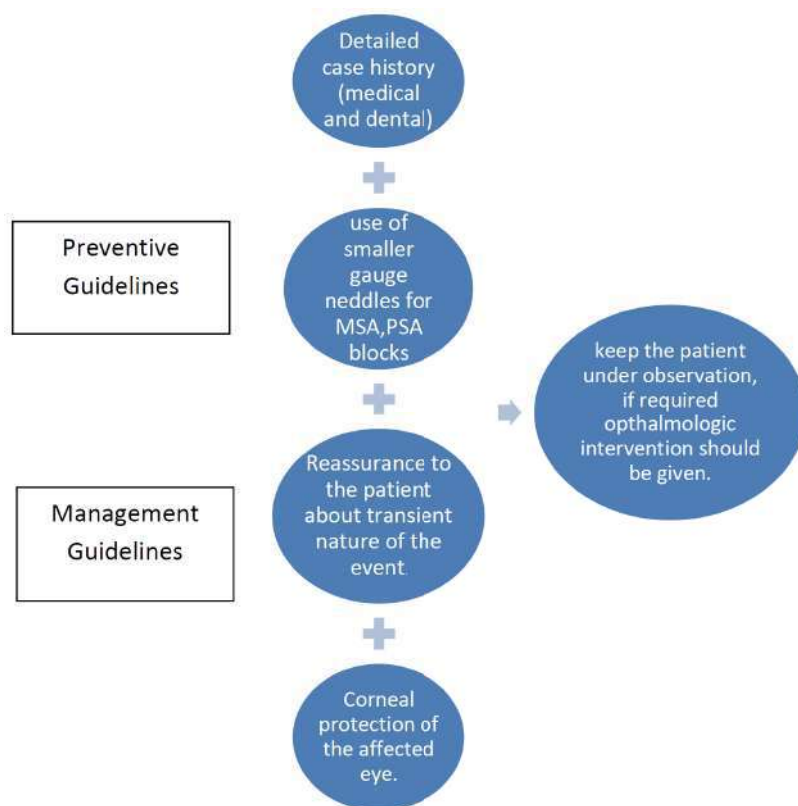

Fig. 3. Preventive and management guidelines

and solaces, patients tend to remain worried. Of all the intraoral procedures performed by a dental surgeon, local anesthetic injections are associated with the mainstream course of ophthalmologic complications. von Arx T et al. [2] reviewed typical incidences of ophthalmologic complications after intraoral local anesthesia and noted that conditions such as diplopia accounted for 39.8% of difficulties in their study. A case of permanent loss of vision in one eye after the administration of intraoral local anesthesia was also reported by Rishiraj et al. in 2005 [4]. Maxillary nerve block causes complications through the following pathways:

1) Direct diffusion of the anesthetic solution from the pterygomaxillary fossa to the orbit, through a defect in the bone.

2) Vascular causes in which the anesthetic solution is diffused through myofascial spaces or bony openings, such as through the inferior orbital fissure, to affect the extra ocular muscles [3].

Confluence of the orbital branch of the middle

meningeal artery and the recurrent meningeal division of the lacrimal branch of the ophthalmic artery leads to paralysis of the lateral rectus muscle and diplopia, in instances of intra-arterial deposition of local anesthesia [5]. Intraluminal injection into the inferior ophthalmic vein can also affect the extrinsic muscles of the eye through the inferior orbital foramen [6]. Diffusion of the anesthetic agent to the orbital cavity can also attain a pathway along the pterygomaxillary fossa through the sphenomaxillary cavity, indirectly impacting nerve endings [7]. As the authors discuss the occurrence of diplopia after posterior superior alveolar nerve block, the literature reveals that diplopia is more common in maxillary than in mandibular anesthesia techniques because of the difference in bone density due to increased dissipation. There are studies suggesting a higher prevalence of ophthalmic complications in female patients compared to men, and more, following usage of 2% articaine than any other local anesthetic agents [8,9]. In the present case, 2% lignocaine HCl was used

as a local anesthetic agent for a posterior superior alveolar nerve block in the recumbent position. Walker et al.[10] identified that the recumbent position of a patient during anesthesia delivery, along with the porous nature of the maxilla, may play a role in causing ophthalmologic complications.

Prevention and management

Awareness of the complications that can occur after a procedure will keep the practitioner prepared to handle the situation. Owing to the fact that ocular complications post-intra-oral local anesthesia are mostly transient, preventive measures taken can reduce anxiety in both patient and doctor. Some authors [5,11] have established preventive and management measures. We have summarized the same for the easier understanding of students and educators (Fig. 3).

In conclusion, complications of local and regional blocks may be less frequent in most cases, but certain conditions such as diplopia and ocular complications occur in rare situations. Correct knowledge and implementation of medical care is helpful in the management of such rare situations.

Abstract

The emerging (COVID-19) pandemic is a global health disaster, caused by infection with severe acute respiratory syndrome coronavirus-2. The disease spreads at an alarming rate all over the world and presents a range of disease manifestations including asymptomatic, mild, moderate and severe symptoms irrespective of age groups. Most patients with severe symptoms exhibit underlying comorbidities such as diabetes, hypertension and obesity. Alternatively, there is an existing evidence for an association between oral health and nonoral systemic diseases. Since the oral cavity is a significant pool for many respiratory pathogens, patients with oral infections are more likely to develop pneumonia as a complication. Therefore, we emphasize that the oral hygiene status has a great impact on the recession and progression of oropharyngeal and respiratory diseases.

INTRODUCTION

The highly contagious viral disease COVID-19 or the severe acute respiratory syndrome is declared as a global pandemic by the World Health Organization (WHO) on March 11, 2020.^[1] A novel coronavirus was later recognized as the causative agent, provisionally named 2019 novel coronavirus (2019-nCoV). Coronaviruses (CoVs) are a group of viruses belonging to the family called Coronaviridae. The subfamily Coronavirinae consists of three genera, alpha coronavirus, beta coronavirus and gamma coronavirus. The spread of infection of severe acute respiratory syndrome CoV-2 (SARS-CoV-2) is either through direct transmission or inhalation of droplets or due to contact with the oral, nasal and eye mucus membranes.^[2] Genomic sequencing and phylogenetic research methods

have supported that the COVID-19-causing coronavirus is a betacoronavirus that belongs to the same subtypes as SARS virus but exhibits a different variant group. The receptor-binding gene site appears to coincide with that of the SARS-CoV and thus suggesting that the same receptor would be used for entry into the cell.^[3]

COVID-19 manifestations can range from asymptomatic state to acute respiratory distress syndrome and multiorgan dysfunction. Most commonly reported are flu-like symptoms of fever, dry cough, malaise, fatigue, myalgia and diarrhea.^[4] Certain risk factors for COVID-19 disease have been reported by the WHO and the Centers for Disease Control and Prevention (CDC) include diabetes, hypertension, aging, immunodeficiency and cardiovascular

diseases.^[5] These risk factors are proposed to have a greater impact with the increased severity of COVID-19; however, there are various other comorbidities that could also be involved in affecting the prognosis. Persons with chronic lung disease, bronchial asthma, obesity, chronic kidney disease and liver disease are also at higher risk. A recent study lists hypertension, obesity and diabetes as the three major underlying conditions with the most unfavorable outcomes in COVID-19 patients requiring hospitalization.^[6] Recently, many studies have revealed the association between oral health status and systemic diseases including systemic infections, cardiovascular diseases and respiratory diseases.^[7] In addition, the impact of good oral hygiene on the reduction of risk in viral acute respiratory diseases has been reported in many studies.^[8] This article gives a bird's eye view about the impact of good oral hygiene status on the recession of oropharyngeal and respiratory diseases.

PATHOGENESIS

Recent studies have reported spike in the mortality rate of COVID-19 ARDS approaching 40%–50%.^[9] The rest of the cases have exhibited deterioration due to aggressive counteracting of the immune system, which is termed as “cytokine storm syndrome”. Certain cytokines such as tumor necrosis factor (TNF), interleukin-6 (IL-6) and IL-1 β when released at increased levels damage host cells to some extent and result in localized edema. During this phase, innate cytokine response could be a predictive factor for the disease progression.^[10] These responses may further stimulate the synthesis of inflammatory mediators and lead to multiorgan failures such as the kidneys and heart due to the hazardous complications of vascular permeability. In addition, a serum marker of hyperinflammation named as C-reactive protein (CRP) is generally elevated. Recent studies have revealed that the patients with elevated levels of CRP have been reported to show a poor prognosis with COVID-19 due to acute inflammatory pathogenesis.^[11] Moreover, the virus affects intestinal lymphocytes, hepatic cells, renal cells and T-lymphocytes inducing the apoptosis of T-cells ensuing in complete collapse of the immune system.^[12]

ORAL HYGIENE AND COVID-19 SEVERITIES

The oral cavity is well represented as “the window to general health.”^[13] Certain systemic conditions such as atherosclerosis, pulmonary infections, diabetes mellitus, osteoporosis and kidney diseases are influenced by oral hygiene status. Patients with poor oral hygiene and periodontal infections tend to suffer from recurrent

gingival inflammation and bacteremia, which activate the host inflammatory response.^[14] This chronic inflammatory condition elicits the release of multiple proinflammatory cytokines such as CRP, TNF- α , IL-1 β and IL-6, in association with bacteremia. These responses tend to increase the susceptibility of the vascular endothelium for injury, thus leading to atherosclerosis. The recent studies have established that the periodontal infection and poor oral hygiene have a strong connection with the risk of acute myocardial infarction and coronary heart disease.^[15] Researchers have suggested that periodontal disease ought to be considered as a major impediment of diabetes. There is better evidence to prove that prolonged hyperglycemia has negative effects on the heart, kidneys, eyes and peripheral nerves.^[16] This condition leads to the release of advanced glycation end products which exhibit a systemic impact that results in the prolonged excretion of cytokines causing inflammation and connective tissue loss.^[17]

Increased cytokine release is another important characteristic feature of severe COVID-19 cases, which exhibit an extreme elevation in inflammatory cytokines including IL-1 β , IL-2, IL-6, IL-7, IL-8, IL-10, granulocyte macrophage-colony stimulating factor (CSF), granulocyte-CSF, monocyte chemotactic protein 1, macrophage inflammation protein-1 α , IFN- γ and TNF- α , 2, 3, 12, and 15 establishing a “cytokine storm.”^[18] A spectacular increase in these cytokines levels over a short time period leads to a series of adverse reactions in the human body which initiate viral sepsis and inflammation-mediated lung injury, leading to respiratory distress, organ failure, shock and potentially death.^[19] Furthermore, in severe COVID-19 cases, elevated levels of inflammatory cytokines may result in shock and multiple organ failure. The constant release of increased levels of cytokines such as CXCL10, CCL7 and IL-1RA is related to lung dysfunction as well as poor prognosis, resulting in fatal outcome.^[20] Patients with poor oral hygiene status can elicit such immune responses which may result in the progression of thromboembolic complications. In other words, good oral hygiene and regular dental visits reduce the chances of incidence and progression of pulmonary diseases.

ORAL MANIFESTATIONS IN COVID-19

Literature reveals that the patients with COVID-19 disease have presented features such as ageusia, nonspecific anosmia and hyposalivation.^[21] Few reports have stated the presence of certain intraoral manifestations such as desquamative gingivitis, herpetic form ulcers on attached gingiva and tongue with multiple irregular ulcers on the dorsal surface in the oral cavity.^[22] Besides these,

the enlargement of submandibular glands and cervical lymph nodes have been noticed. The presence of ACE2 receptors on target cells could be the possible reason. These receptors help in the binding of SARS-CoV-2 virus spike proteins to the cells which pave way for consequent infections.^[23] The presence of ACE2 expressing cells in large numbers in the epithelial cells of the oral and nasal mucosa attributes to ageusia and anosmia, respectively.^[24] The oral conditions presented by some patients in few studies support the hypothesis that they are extremely indicative of secondary lesions ensuing due to the deterioration of systemic health or due to therapeutic measures for COVID-19. In COVID-19 patients, the presence of some oral manifestations including ageusia, traumatic ulcers, petechiae, candidiasis, HSV-1 infection and geographic tongue need to be considered. Various associated therapies in COVID-19 infection could perhaps contribute to adverse consequences regarding oral health such as unexplained oral ulcerations, recurrent oral herpes simplex virus (HSV-1) infection, opportunistic fungal infections, fixed drug eruptions, ageusia and xerostomia as a result of the altered immune system and its responses.^[25]

Among the opportunistic fungal infections, mucormycosis though rare yet is the rising fungal infection in COVID-19 cases. The causative fungi belong to Mucorales. Manifestations include cutaneous, mucosal, sinusitis, pulmonary, gastrointestinal or sometimes dissemination. These fungi affect the immunocompromised patients those that are on high-dose glucocorticoids, hemodialysis and uncontrolled diabetes mellitus.^[26] In a healthy individual, the spores and hyphae are attacked by immune cells and destroyed by monocytes, macrophages and polymorphonuclear phagocytes. When patients exhibit diminished immune status with low phagocyte count, altered phagocyte function or uncontrolled diabetes mellitus, they become progressively susceptible to the invasive type of mucormycosis.^[27]

OROFACIAL ADVERSE EFFECTS FOLLOWING COVID-19 VACCINES

Certain medication-related events such as adverse drug reactions (ADRs) are possibly life-threatening consequences due to the usage of medicines as well as vaccines. Hence, it is significant to recognize the adverse events on time to reduce the conceivable harm.^[28] Therefore, health professionals including dentists should be primed to diagnose orofacial ADRs probably being drug induced. The clinical trials and the development of effective vaccines against SARS-CoV-2 virus have been extremely progressing.^[29] At present, two RNA-based COVID-19 vaccines have

been permitted for emergency use and authorized for marketing by the regulatory agencies in Europe and America and are being used all over the world. Of late, another vaccine (AZD1222, Oxford–AstraZeneca) has been granted for use in the UK. Recent literatures have revealed the data on preliminary efficacy and safety for both BNT162b2 (Pfizer-BioNTech) and mRNA-1273 (Moderna) vaccines.^[30] As several billion doses of vaccination need to be administered, it is possible that an ample number of adverse events to be reported. The knowledge of the dentist regarding orofacial manifestations will enhance the diagnosis, management and reporting of vaccine-related adverse events. Recent study shows that COVID-19 vaccines have possible yet rare orofacial side effects including anaphylaxis associated with facial swelling, Bell's palsy and swelling of the face, lips or tongue. In addition to orofacial manifestations and systemic ADRs with anaphylaxis, both of the vaccines were seen associated with acute peripheral facial paralysis. It has been reported that there were two serious adverse events regarding facial swelling seen only with respect to mRNA-1273 vaccine recipients. The onset of the adverse event was reported 2 days after vaccine administration and was probably related to vaccination according to MHRA (UK).^[31] Finally, it has been concluded that both BNT162b2 and mRNA-1273 COVID-19 vaccines are associated with ADRs including orofacial manifestations with heterogeneity expression all over the world.

CONCLUSION

Patients with COVID-19 exhibit a range of disease manifestations including asymptomatic, mild, moderate and severe symptoms and high cytokine levels, which can be considered potential biomarkers for disease progression. The specific immune responses of COVID-19 tend to establish cytokine storm and thromboembolic complications which can further lead to multiple organ dysfunctions. In addition to this, compromised immune status leads to the rise of certain opportunistic infections such as mucormycosis which is rare yet extremely exhibit fatal outcome. On the other hand, poor oral hygiene can contribute to altered immune responses. Therefore, improving oral hygiene and reducing gingival and periodontal inflammation may reduce the risk of complications arising due to COVID-19 disease. Since knowledge about this concept and orofacial adverse effects due to vaccination is brainstorming, further researches are required to report cases of COVID-19 seen associated with oral diseases to add to the pool of knowledge on a comprehensive level.

Marsupialization of odontogenic keratocyst using thermoform surgical splint in a pediatric patient, with 3-year follow-up

Srinivas Nallanchakrava, Mallela George Manoj Kumar, Dwitha Animireddy, Garikina Manasa

Department of Pediatrics and Preventive Dentistry, Panineeya Mahavidyalaya Institute of Dental Sciences and Research Centre, Hyderabad, Telangana, India

Abstract

Odontogenic keratocyst (OKC), also known as keratocystic odontogenic tumor, is categorized as one of the developmental epithelial cysts, which accounts 10%–20% of all cystic lesions in jaws. Considering its high recurrence rate, combative treatment modalities such as enucleation and jaw resection are suggested. This case report aims to emphasize clinical, radiological and histological overview of OKC with conservative approach marsupialization using thermoform surgical splint in a 9-year-old female patient with no recurrence at 3-year follow-up.

Keywords: Marsupialization, odontogenic keratocyst, thermoform splint

INTRODUCTION

Odontogenic keratocyst (OKC) that originates either from a dental lamina or primordial odontogenic epithelium^[1,2] is a benign tumor of the jaws, and the term was introduced by Philipsen in 1956.^[1,3] According to the World Health Organization's (WHO) 1992 classification, OKCs are typed under developmental (dysembryogenetic) cysts^[3] and were designated in 2005 as a keratocystic odontogenic tumor^[4,5] which is defined as "a benign uni or multicystic, intraosseous tumor of odontogenic origin, with a characteristic lining of parakeratinized stratified squamous epithelium, and potential for aggressive, infiltrative behavior."^[5,6] In 2017, the fourth edition of the WHO/IARC Classification of Head and Neck Tumors were published where keratocystic odontogenic tumor is back into the cystic category as OKC.^[1,7] It is

frequently reported in the second to fourth decade of life and relatively less in the first decade.^[2] It has a multicentric growth pattern, infiltrating through cortical bone and extending into adjacent soft tissue.^[8] Conservative treatments are widely employed in children to avoid complications associated with radical operations.^[9] Marsupialization is one such conservative treatment, proved to be effective treating cysts among children and adolescents which secures adjacent vital anatomical structures such as inferior alveolar nerve, maxillary sinus and developing dentition.^[10]

CASE REPORT

A 9-year-old female patient reported to the Department of Paediatric and Preventive Dentistry with a complaint

of pain and swelling in right lower back tooth region. On general examination, the patient was healthy. The patient had a history of pulp therapy in 84, 3 years back, and complained pain in the same region. Extraoral examination revealed facial asymmetry due to swelling noted on lower right side of face, with no visible pulsations or pus discharge [Figure 1a]. A single diffuse swelling, approximately 3 cm × 3 cm in size, extended anteriorly 1 cm behind the right corner of mouth to 3 cm posteriorly. Superiorly, extended 3 cm below the ala-tragal line and inferiorly to lower border of mandible. No paraesthesia was noted. Submandibular lymph nodes on right side were palpable, tender, mobile and firm in consistency. On intraoral examination, vestibular obliteration in right mandibular region from permanent lateral to the first molar with normal overlying mucosa was seen [Figure 1b]. Swelling was tender, nonfluctuant, bony hard in consistency. Other clinical findings included disto-proximal caries in 74 and deep occlusal caries in 36 [Figure 1b and c]. Panoramic radiography and cone beam computed tomography scan revealed a single homogenous well-defined radiolucency on the right body of mandible measuring approximately 2.5 cm × 3 cm in size, extending antero-posteriorly from distal aspect of 83 to distal side of 46 and expansion of the lesion resulted in displacement of permanent canine tooth bud downward and forward below incisors and premolars tooth buds downward and backward below permanent molar, 1 cm above the inferior border of mandible [Figure 1c]. The roots of deciduous first and second molar were resorbed. Inferior alveolar canal was not seen. Expansion of buccal and lingual cortical plates on the right side of mandible was observed [Figure 1d]. Based on clinical and radiological findings, the provisional diagnosis of radicular cyst was made. Histological examination was planned to differentiate from OKC, dentigerous cyst,

buccal bifurcation cyst and unicystic ameloblastoma. Enucleation was common treatment option. However, due to large size of the lesion, age, anatomical structures, and teeth involved, incisional biopsy was done followed by marsupialization after informed consent was obtained from the parent. Fine needle aspiration cytology was done using 5 ml syringe where a milky-yellow liquid content was obtained [Figure 2a]. Extraction of 84, 85 was performed and red wine-colored material appeared inside the cavity was collected [Figure 2b]. An impression was made followed by fabrication of thermoform surgical splint [Figure 2c], extending into surgical site with buccal and lingual flanges to support fragile walls from collapse [Figure 2d and e]. Parents were given oral hygiene instructions regarding maintenance of splint, and irrigation of socket with betadine, and saline thrice daily. The patient was explained regarding the treatment plan of 36, 74, but the patient was intended to get it done later as they were more worried about the existing lesion. Cytopathologic examination of the aspirate showed dense population of neutrophils, lymphocytes, foamy macrophages, few multinucleate giant cells and keratinocytes against hemorrhagic background suggestive of keratin filled lesion. Biopsy revealed parakeratinized stratified epithelial lining with prominent columnar basal cell layer, surface corrugation, and neutrophils, lymphocytes arranged against extravasated red blood cells [Figure 2f], which confirmed the diagnosis to be OKC. Follow-up was done every 3 days till 1st month which showed occlusal movement of developing tooth bud clinically, as well as reduction in radiolucency radiographically [Figure 2g]. Later, the patient was reviewed every 6 months till 3 years, in which there was a gradual reduction in radiolucency, occlusal movement of developing tooth buds and accordingly surgical splint was refabricated. During the 2nd-year follow-up, endodontic treatment was performed in 36 followed by composite inlay. By the end of 3 years, there was complete healing of the lesion with eruption of all permanent teeth [Figure 3a-f].

DISCUSSION

OKCs are common developmental odontogenic cysts occurring three times more often in the mandible than the maxilla and is most frequently seen in the region of canine to premolar, mandibular retromolar, ramus areas and maxillary second permanent molar area.^[3] It should be often differentiated from Dentigerous cyst, radicular cyst and lateral periodontal cyst which are other endodontic lesions.^[11] Radiographically OKCs display a radiolucency extending along the length of the mandible displacing developing teeth in children and adolescents. Histopathologically, OKCs are characterized by 5–8

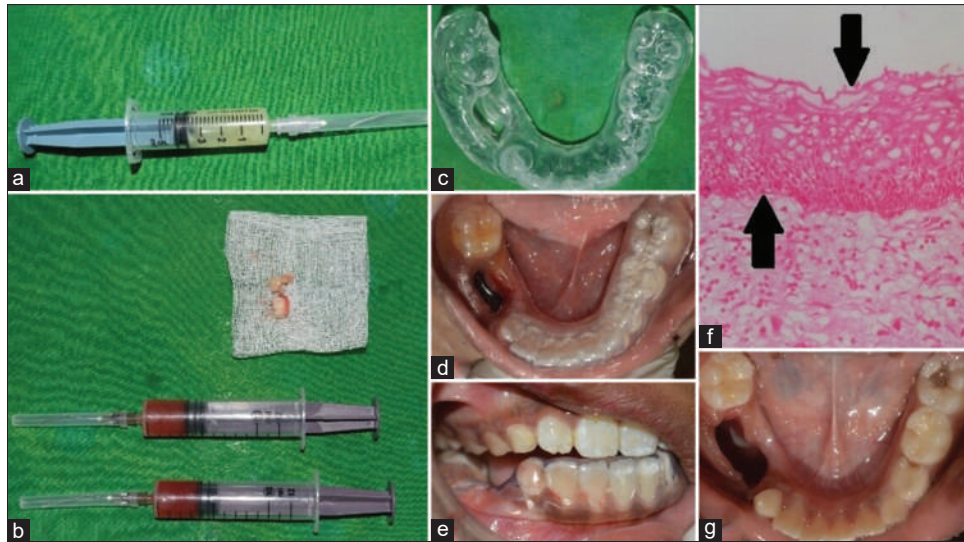

Figure 2: (a) Aspirated fluid (milky yellow in color) (b) Extracted 84, 85 and red wine-colored fluid collected (c) Fabricated thermoform surgical splint (d and e) Inserted marsupialization splint (f) Histologic picture showing parakeratinized stratified epithelial lining with prominent columnar basal cell layer (arrow), surface corrugation (arrow) (H&E stain, x40) (g) Follow-up after 1 month

layered parakeratinized stratified squamous epithelium lining connective tissue capsule. Basal layer has palisade arrangement of hyperchromatic nuclei in columnar epithelial cells. The epithelial projections are absent in epithelial-connective tissue junction. The consistency of luminal content can be described as a “straw-colored fluid,” “thick pus-like” material or a caseous, cheesy, thick, milk-white mass which was similar in this case.^[5] Treatment of OKCs remains controversial because of their higher recurrence potential,^[12] and options include decompression, marginal resection, *en bloc* resection and adjuvant therapy, like cryotherapy, peripheral ostectomy and

Carnoy’s solution.^[2] However, marsupialization (Partsch I procedure)^[7] is reported to be the treatment of choice in large cysts involving multiple unerupted teeth and anatomic structures. It aims to reduce the size of the lesion thus preventing extensive surgery, preserving vital structures.^[9] In literature, the term marsupialization is often used interchangeably with decompression, but they are distinguished as decompression is any technique that reduces the pressure within a cyst, while marsupialization is a process of converting cyst into an open pouch that communicates with the oral cavity.^[7] However, both the procedures allow new bone to fill the defect. Studies have shown that more effective results were observed after marsupialization in lesions of the mandibular body than in ramus.^[13]

Despite having advantages, it has few limitations like prolonged healing period, discomfort to the patient, requirement of irrigation twice daily and weekly modification of surgical splint maintaining the cystic opening.^[7] Various devices such as tubes, gauzes, obturators and acrylic stent can be used for cystic window, but due to drawbacks like retention failure, increased porosity, irritating effect of residual monomer and difficulty in processing, usage of thermoformed appliances has gained high demand.^[14] In this case, thermoform splint was used which is a polyoxymethylene-based material made up of acetal resin. It is retained in an adequate position by negative pressure created intraorally. This obturator has advantages like easy removal to irrigate the cavity, nontoxic, nonallergic, flexible, resists wear and fracture, making it an ideal material of choice as surgical stent.^[14] Ziccardi *et al.*

used marsupialization stent along with space maintainer to preserve space for unerupted teeth.^[10] In the present case, thermoform marsupialization splint itself maintained space between existing dentition and allowed the displaced teeth to erupt in proper alignment without requirement of an additional space maintainer or orthodontic traction.

Literature has reported that recurrence rate of OKC varies from 35% to 50% and 21.4% among lesions treated by marsupialization.^[13] An immunohistochemistry study noted that after marsupialization, the epithelium thickness was increased, and the keratinized epithelium was changed to a hyperplastic and nonkeratinized stratified squamous epithelium.^[7] There is a histological transformation of 23 aggressive keratocysts to either less aggressive OKC or nonkeratocysts before and after marsupialization. Interleukin 1 and Ki-67 reduction was also observed in many cases, which is considered to be the factor for decrease in volume of the cysts^[15] allowing new bone to fill the defect.^[7] Thus, growth characteristics of OKC may become less aggressive during the course of marsupialization.^[13] implying that recurrence rate is not affected by it.^[7] According to Forssell *et al.*, an active follow-up performed annually during a 3-year period in pediatric patients might be sufficient, to ensure absence of recurrence and adequate eruption of the permanent teeth.^[13]

In conclusion, the diagnosis of OKC can be confirmed histologically along with radiological findings. In the selection of the most appropriate treatment, one must consider patient factors such as age, general medical condition and lesion characteristics. Considering the young age of the patient, subsequent growth of mandible and facial contour, treatment by marsupialization was performed in this case without any recurrence at 3-year follow-up which was an unique scenario. Although marsupialization is an unconventional method of treating OKC, it is a very effective method in children where there is proximity of lesion to the developing tooth buds and vital structures in the jaws. For the treatment success, regular follow-ups, along with patient awareness in maintaining oral hygiene, are important.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient (s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal.

The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Abstract---Introduction: The restorations to anterior teeth in children is very significant. Hence in this study we compared efficiency of strip crowns versus primary anterior zirconium crowns in 3 to 6 year old children. Material and Methods: We selected 100 children of ages 3-6 years to receive the anterior crowns, attending the institution department of pedodontics. They were divided to 50 each of zirconia and strip crown groups. The various parameters were checked at 3,6 and 12 months. Values were compared keeping $p < 0.05$ as significant. Results: Zirconia crowns showed significantly lower plaque

accumulation, gingival bleeding restoration failure, at the 3- and 6-months no, but more wear to opposing teeth. With regards to recurrent caries no significant difference was found between the two crowns. Conclusion: Based on our data we conclude that overtime teeth covered with zirconia crowns show better gingival health and less bleeding, plaque accumulation as well as less loss of material. On the other hand, zirconia can cause more loss of opposing tooth structure.

Keywords---Primary anterior teeth, Strip crowns, Zirconia crowns.

Introduction

The children are more prone to caries than adults due to multiple reasons. Providing care to children who are considered to be at risk of caries, is to be done under specialist care. For the anterior primary teeth caries there are various restorations. Primary incisors with large or multi-surface caries can be restored with resin composite strip crowns if there is sufficient tooth structure after removing all carious tissues [1]. When remaining tooth structure is less or isn't enough for bonding, pre-veneered aesthetic crowns is a favorable solution. Stainless steel crowns with cosmetic facing have good aesthetics and good retention even with minimal remaining tooth structure. Moisture and hemorrhage control are not critical with these restorations which need minimal chair time and offer full coverage and protection.

Off late, zirconia aesthetic crowns for children appeared in the market. Zirconia has properties like metal and esthetics of the teeth, and the ready to use zirconia crowns are available for primary teeth. Although there is high acceptance of zirconia crowns, the literature lacks solid proof for their pediatric clinical performance [2-5]. There are limited clinical studies that are currently ongoing, however until the outcomes of adequate number of prospective researches with good long-term follow-up. Hence in this study we compared efficiency of strip crowns versus primary anterior zirconium crowns in 3 to 6 year old children.

Material and Methods

We selected 100 children of ages 3-6 years to receive the anterior crowns, attending the institution department of pedodontics. After obtaining the ethics clearance the consent was taken from the guardian of the children. We included both the genders for the study. Subjects with no major health issues, or bruxism were selected for the study. Any subjects with medical issues or problems were excluded.

The subjects were randomly divided to two groups to receive the zirconia and strip crown groups. The restorations were done according to the treatment protocols and the manufacturer's guidelines. The Gingival health, Plaque index, Secondary caries, Restoration failure, Tooth wear were evaluated. The subjects were followed up for a period of 3,6 and 12 months and at each visit the above parameters were

noted. These readings were compared using Chi square test keeping $p < 0.05$ as significant.

Results

We observed that significantly more teeth in the strip crown group were bleeding compared to the zirconia groups at the 3, 6-months follow-up. Table 1 We observed that that none of the teeth covered with zirconia crowns developed caries during the entire period of follow up. On the other hand, teeth that received strip crowns restorations had no recurrent lesions in the 3- and 6-months follow up but when it reached the 12-months follow up, 6.7% presented with recurrent caries. Table 2 We observed that at three months follow up, no failures was noticed in both groups. In the zirconia crown group, two crowns were lost completely in 6 and 12 months follow up due to trauma caused by falling of patients and hitting hard objects. On the other hand, failure was more in the strip crown group as 11.7% showed small but noticeable area of material marginal loss and 1.7% presented with large loss of crown during the 6 months follow up. Also, this loss increased with time to reach 30% small but noticeable area of loss of material and 8.3% large loss of restorations were clinically observed for crown by the 12 months follow up. Table 3 We observed that incisal and labial surfaces of the teeth opposing the full-coronal restorations were clinically observed for any sign of abrasion. 10 teeth opposing to zirconia crowns showed loss of enamel surface characteristics and minimal loss of contour. Discussion

In assessment of gingival health, this study shows better gingival response in zirconia crowns which can be explained by the fact that zirconia is biocompatible and possesses a polished and smooth surface leading to less plaque accumulation and hence less gingival irritation [6–8]. This is similar to the study of Walia et al. [3] who evaluated anterior primary crowns for 129 patients. In agreement with our study, Walia et al. [3] also reported that zirconia crowns showed improved gingival health due to less plaque accumulation when compared to composite strip crowns and pre-veneered SSCs. Our data showed that none of the teeth covered with zirconia crowns showed recurrent caries during the entire follow up. In contrast, teeth restored with composite resin strip crowns showed that 6.7% developed recurrent caries in the 12-months follow up. Significant factors that influence development of caries are poor oral hygiene and high cariogenic diet.[9,10] A recent study by Holsinger et al. [4] reported results similar to our study's in their evaluation of 57 crowns treated with zirconia for primary anterior teeth in 18 patients. Their and other similar studies showed no recurrent caries after a follow-up period of 24 months. [6-10] The greater restoration failure of the composite strip crowns in this study may be explained by the fact that treatment was done under nitrous oxide sedation and physical restrains to manage the children behavior. Regarding the zirconia crowns, the success rate in this study was 98.3% by the end of the 12 months follow up. Only two crowns failed due to trauma. Current research on the clinical success of prefabricated primary zirconia crowns for primary incisors is still limited. Walia et al.[3] reported the retention rate of zirconia crowns as 100% after 6 months. These crowns have no facial upper structure, as they are made up of solid zirconia leading to no chance of facial veneer fracture. In our study seven teeth opposing to zirconia crowns

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

showed loss of enamel surface, minimal loss of contour compared to 100% no loss of enamel surface characteristics in strip crown group. This results is in agreement with Walia et al. [3] who found four opposing primary teeth out of 38 zirconia crowns having loss of enamel surface characteristics and minimal loss of contour. Although one of the inclusion criteria was selecting patients with positive behaviour, some children occasionally became uncooperative due to prolonged procedure. Another limitation was the high cost of Zirconia crowns. A longer follow-up studies on zirconia crowns is suggested.

Conclusions

We can conclude that zirconia crowns showed better gingival health and less bleeding, plaque accumulation as well as less loss of material. On the other hand, zirconia can cause more loss of opposing tooth structure.

Comparative evaluation of chelating efficacy of nano-chitosan, pomegranate extract, and ethylenediaminetetraacetic acid on primary radicular dentin: An *in vitro* study

G. Deepthi Nirmal, A. J. Sai Sankar, E. Sridevi, M. Sridhar, K. Siva Sankar, P. Raja Satish¹

Departments of Pedodontics and Preventive Dentistry and ¹Oral and Maxillofacial Surgery, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

ABSTRACT

Background: Irrigation is a crucial aspect of root canal treatment, and it is imperative to employ chelating agents to eliminate the smear layer during biomechanical preparation. They in turn react with mineral content of dentin, leading to decreased strength and increased susceptibility to fracture. **Aims:** This study aimed to assess and compare mineral loss and microhardness from primary root canal dentin following the usage of different irrigating solutions and determine the least detrimental irrigant among the tested solutions. **Materials and Methods:** Sixty-six primary anterior teeth were divided into three groups with 22 in each- Group I: 17% ethylenediaminetetraacetic acid (EDTA) Group II: 0.2% Nano chitosan Group III: Pomegranate extract. The decoronated teeth were split longitudinally. Half of it was directly subjected to Vickers test, and the other half was immersed in a magnetic stirrer bath containing test solution to record the mineral loss from solution. Postmicrohardness values were recorded on the specimen and compared with initial values. **Statistical Analysis Used:** Statistical analysis was done using SPSS software (Version 20, SPSS, IBM, Armonk, NY, U. S. A). **Results:** Descriptive statistics were calculated, and the groups were compared using analysis of variance test and *post hoc* Tukey test. Pomegranate extract showed least effect on mineral content and microhardness compared to 17% EDTA and 0.2% nano chitosan. $P \leq 0.05$ was considered statistically significant. **Conclusion:** Pomegranate aril extract showed better results with selected parameters.

that cannot be reached directly by instrumentation. Regardless of the instrument and technique employed, the maneuver of endodontic instruments against dentinal walls consequently promotes the formation of smear layer.^[2,3] The complete removal of smear layer requires chelating agents, followed by tissue solvents because no single solution can furnish both effects alone. Therefore, ethylenediaminetetraacetic acid (EDTA) and sodium hypochlorite solutions have been jointly advocated as an effective irrigation regimen.^[4]

Chelating agents were introduced to endodontics by Nygaard-Ostby^[5] as an adjunct to prepare narrow and calcified root canals and smear layer removal. They increase the penetration of irrigants into dentinal tubules, thus allowing adequate disinfection and a reduction in dentin microhardness that facilitates the access and action of endodontic instruments in the root canals.^[6,7] However, usage of endodontic irrigants like EDTA causes dentinal cracks and alterations in the chemical composition of dentin particularly, the calcium and phosphate ratio which in turn changes the microhardness, permeability, and solubility characteristics of dentin, thereby adversely affecting sealing ability and adhesion of dental materials to dentin.^[8]

Recently, the global scenario is inclining towards natural products like Chitosan which is a polysaccharide biopolymer produced by the alkaline deacetylation of chitin, the principal component of crustacean and shrimp exoskeletons.^[9] Chitosan contains ideal properties including biocompatibility, biodegradability, bioadhesion, high chelating ability for various metal ions in acidic conditions, lack of toxicity, and even antibacterial activity. Owing to these properties, proposed uses of chitosan in dentistry are diverse. It was used as an irrigant in several studies^[10,11] and Bastawy *et al.*^[9] reported that even at the lowest concentration, chitosan removed the smear layer as effective as or more than EDTA. Ikono *et al.*^[12] found that chitosan nanoparticles (Cs-NPs) have smaller size and better penetration than chitosan, and this property makes it unique with superior qualities.

Among the myriad of herbal alternatives available, pomegranate (botanical name: *Punica granatum*) finds a noteworthy mention of its several antioxidant activities, including radical scavenging ability, ferrous ion chelating, and ferric ion reducing power.^[13] Pomegranate is now finding prime uses in the dental arena as well. Prior studies^[14,15] employing the pomegranate rind or extract of pomegranate suggest that pomegranate has effective antimicrobial activity, but the chelating potency of pomegranate extract in endodontics has been left unexplored. Hence, an attempt is made to study pomegranate aril extract's effect on the primary radicular dentin.

Even though plentiful studies regarding the effect of root canal irrigants on permanent root dentin are available in the literature,^[3,8,11] their impact on primary root canals is quite limited. Hence, the results obtained cannot be pertinent to primary teeth due to morphological differences such as dentinal tubules, accessory canals, root tip bifurcation, and compositional variations.^[16] Henceforth, the present study was aimed to evaluate the effect of 17% EDTA, 0.2% Nano-chitosan and pomegranate aril extract as irrigating agents on the microhardness and mineral content of primary radicular dentin.

Materials and Methods

The present laboratory study investigated the effect of various root canal irrigants on the calcium and phosphate content and microhardness of primary root dentin using the Atomic Absorption Spectrophotometer (AA-6300, Shimadzu, Kyoto, Japan); Vandomolybdophosphoric acid method, and Vickers Hardness Test, respectively. After obtaining clearance from the institutional ethical committee, the present *in vitro* study was planned with a sample size of 70 teeth which was calculated using G * POWER 3.1.9.2 software with a power of 80%, effect size of 0.4, and an alpha error of 5%.

The sample included human primary anterior teeth which were un-restorable due to caries or trauma or over-retained. These teeth were collected from the tooth bank in our institute and stored in distilled water at room temperature (37°C) until use. The soft and hard debris on the root surfaces was cleaned using hand scaler, decoronated at the cemento-enamel junction, and at the root apex to obtain 10 mm standard-sized specimens using a low-speed diamond disc. Roots were sectioned longitudinally into two halves, and pulp tissue was removed using a brush. Four samples were discarded due to improper sectioning, and the remaining 66 samples were randomly divided into three groups of 22 specimens in each using computer randomization method depending on the irrigating solution used. Group I: 17% EDTA, Group II: 0.2% nano-chitosan and Group III: Pomegranate aril extract.

Before commencing the experiment, 17% EDTA solution (Prevest Denpro Ltd, Jammu) was procured. 0.2% nano chitosan solution was made by dissolving 0.2 g of chitosan powder (size 395 ± 98.5 nm) (Aura Biotechnologies, Chennai) in 1% acetic acid with the volume of 100 ml. To obtain a homogenous solution, the mixture was stirred with a magnetic agitator for 2 h. Chitosan was synthesized from shrimp shells (degree of deacetylation >75%) using ionic gelation method and polyanion tripolyphosphate (TPP) as crosslinker.^[11]

Fresh pomegranate fruits were brought to the laboratory, cleaned in running tap water; surface sterilized using 70% alcohol, and then rinsed with

sterile distilled water. Pomegranate aril juice was freshly prepared after removing the rind and separating the arils. The arils were blended in a domestic mixer without dilution. The blend was first filtered through a sieve followed by centrifugation of the obtained extract to precipitate the residual waste, and the supernatant clear solution obtained was again passed through a filtration assembly using a series of membrane filter papers of 0.45 microns.^[17] The final extract thus obtained was placed in the ultraviolet (UV) sterilizer and used in the study. Freshly prepared undiluted and filtered pomegranate aril extract has been used to know its indisputable effect on human radicular dentin and to avoid any bias that might occur with the use of preservatives. The pH of the test solutions of different groups I, II, and III were 7.2; 3.5; and 3.4, respectively, which was determined using a pHmeter with an accuracy of ± 0.002 .

In each group, one-half of the specimen was immersed in a magnetic stirrer bath containing 10 ml of test solution for 5 min. Accordingly, 1 ml of solution was aspirated from the bath after 5 min for Calcium (Ca) analysis using Atomic Absorption Spectroscopy technique.

The phosphate level of the solution was calculated using the vanadate-molybdate method which is based on the APHA Standard Method 4500-P C. 0.25 ml of vanadate-molybdate reagent was added to 1 ml of sample irrigating solution from the magnetic stirrer bath and the solution was mixed by pipetting up and down for several times till yellow color is developed in the cuvette. This sample was placed in the UV-visible spectrophotometer (Shimadzu UV-1700 Pharma Spec) to get the absorbance value of phosphate converted to phosphate concentration in parts per million.^[18]

The other half of the specimen was mounted horizontally on an acrylic block and the dentin surface was polished with silicon carbide sandpaper with three progressively increasing grit sizes (400, 600, and 1200, respectively) to obtain a smooth surface for analyzing surface microhardness using digital microVickers hardness tester under an indentation load of 150 g with an indentation time of 15 s. The mean average of the three indentations taken on the middle third of the root dentin was considered as baseline hardness value.

After immersing in the respective irrigating solutions, the part of the specimen used for mineral loss analysis was flushed with saline, air dried, mounted on an acrylic block, dentin surface was polished using silicon carbide sand papers (400, 600, and 1200) and subjected to Vickers test. The difference between initial and final microhardness was noted.

A single operator performed the entire procedure. However, to avoid bias, a second operator who was unaware of the prior results evaluated the samples

randomly. Interexaminer reliability was assessed by the kappa test. As an interexaminer reliability statistic of 0.93 was achieved indicating excellent agreement (Intraclass correlation coefficient = 0.93), the scores given by the first investigator were only considered for the analysis. Statistical analysis was done using SPSS Version 20 (SPSS, IBM, Armonk, NY, U. S. A), and the groups were compared using analysis of variance test and *post hoc* Tukey test as necessary. The $P \leq 0.05$ was considered statistically significant.

Results

The mean calcium and phosphate loss in the three groups after placing in the respective irrigants ranged from 1.9 ppm to 24.26 ppm and 2.6 ppm to 29.3 ppm respectively, with highest loss seen in group II followed by I and III [Table 1].

The preimmersion microhardness values of the samples ranged between 56.44 and 56.97 Vickers hardness numbers (VHN) which were not statistically significant ($P > 0.05$). However, when the pre and post-immersion microhardness values were compared, groups I and II showed statistically significant change from their baseline values ranging from 19.74 to 20.26 VHN. Whereas in group III samples, not much difference (1.23) was noticed between pre and postmicrohardness values, although the change was statistically significant ($P < 0.05$) [Table 2].

On intergroup comparison, the mean difference in calcium mineral loss varied between 17.75 and 22.36 with least variation recorded between groups I, II and the highest change observed between groups II, III. The amount of loss noticed was statistically significant ($P < 0.05$) among all the three groups [Table 3]. The mean difference in phosphate loss ranged between -23.73 and 26.67 with least change recorded between groups I, III and highest change observed between groups II, III. A statistically significant difference in phosphate loss was noticed on an intergroup comparison between I, II and II, III with no significant difference in phosphate loss between I and III, the value was 2.93 [Table 3]. The microhardness values span from -17.78 seen between groups I and III to 0.34 observed between groups I and II. As shown in Table 4, it was evident that intergroup comparison of

Table 1: Mean calcium and phosphate loss following the usage of different irrigating solutions

Variable	Group	Mean (ppm) \pm SD
Calcium loss	17% EDTA	6.5 \pm 1.58
	0.2% nanochitosan	24.26 \pm 3.86
	Pomegranate aril extract	1.9 \pm 0.82
Phosphate loss	17% EDTA	5.59 \pm 2.08
	0.2% nanochitosan	29.32 \pm 7.11
	Pomegranate aril extract	2.65 \pm 1.24

EDTA=Ethylenediaminetetraacetic acid; SD=Standard deviation

Table 2: Pre-and post-immersion microhardness values

Groups	Premicrohardness	Postmicrohardness	Mean difference between pre-and post-immersion microhardness values	P

*P<0.05=Statistically significant. EDTA=Ethylenediaminetetraacetic acid

microhardness postimmersion showed no significant difference between groups I, II but these solutions have significant difference with group III [Table 4].

Thus, it can be hypothesized that pomegranate aril extract demonstrated minimal effect on calcium, phosphate loss and microhardness values. Although 17% EDTA showed less mineral loss than 0.2% nano chitosan, the variation in microhardness was analogous with it. Novel irrigating solution nano chitosan had the most significant effect on calcium and phosphate loss and microhardness values.

Discussion

The root canal system is remarkably complex and variable, limiting the ability to clean and disinfect it predictably. Peters *et al.*^[19] stated that irrespective of the instrumentation technique used, 35% or more of the root canal surfaces, including canal fins, cul-de-sacs, and isthmi remain un-instrumented with the evidence derived from their study on permanent teeth using micro-computed tomography scans before and after mechanical instrumentation. Thus, the use of chemical adjuncts is considered a *sine qua non* in root canal treatment.^[20,21] Concerning primary teeth, in particular, more ictus is on chemical means with limited mechanical debridement.^[22] Therefore, irrigation is an indispensable part of root canal debridement.

An ideal irrigant should have many prerequisites.^[23,24] In addition, the choice of a cleanser in the pulpal therapy of primary teeth should have auxiliary requirements such as: They must not irritate the periapical tissues to avoid harming the germ of the permanent successor tooth, should facilitate easy instrumentation in the ribbon shaped canals, increase root dentin permeability without altering the microhardness of primary teeth.^[25]

The most common chelating solutions are based on EDTA, which reacts with the calcium ions in dentin and forms soluble calcium chelates.^[10] Chelating solutions remove dentin calcium ions, favoring smear layer removal and altering the microhardness. Baldasso *et al.*^[26] have hypothesized that these changes could increase the tooth's susceptibility to fracture. Biomaterials like Cs-NPs reduce the possibility of bacterial penetration, prevents dentinal micro-fractures, and improves the mechanical properties of the root dentin.^[27] Its high chelating capacity for different metallic ions and low cost, made it a preferable irrigant for the study. Natural phytochemical pomegranate has active components such as organic acids and bioactive compounds like phenolics and flavonoids, principally anthocyanins that inhibits the plaque-forming microorganisms and effectively removes smear layer in the root canals.^[28]

This study quantified the calcium ions chelated by different solutions from the root canal dentin by atomic absorption spectroscopy, a susceptible procedure popular for its elemental selectivity.^[29] Among the various phosphate determination methods, spectrophotometry involving molybdovanadate and ammonium molybdate is most widely used for biological applications as it is more sensitive, and the preparation of reducing agent is easy.^[30]

Microhardness determination is sensitive to composition and surface changes of the tooth structure; hence, it can provide indirect evidence of mineral changes, either loss or gain in dental hard

tissues.^[9] Previous investigations have demonstrated that Vickers microhardness test is an appropriate and practical tool for evaluating dentin surface changes treated with chemical agents.^[9,31] The fact that there were no statistically significant differences between the pretreatment microhardness values of all the tested groups proved that the specimens were standardized. The resulted difference in microhardness values was because of the different irrigating solutions used. In the current study, the longitudinal sectioning of the roots was preferred as it could show an accurate representation of clinical situation,^[6] and as the irrigants first contact the most superficial layer of root canal dentin, its microhardness was measured.^[32] In the present study, the root canals were not prepared before analysis; thus, no smear was present on the dentin surface. This step was omitted so that calcium and phosphate loss from intact root dentin could be measured, avoiding any possible contamination of readings that could result from calcium and phosphate being incorporated into loosely bound dentin.^[8]

The rationale behind using 17% EDTA was to test a low yet commonly used EDTA concentration on calcium and phosphate removal. 0.2% chitosan application for 5 min is the most viable combination for its use on root dentin and smear layer removal.^[33,34] Hence, a similar concentration of nano-chitosan has been used for equitable comparison. In the present study, a 5-min exposure time was advocated for each chelating solution as it may simulate the clinical application time of the irrigant solution.^[35]

Atomic absorption spectrophotometric analysis of calcium and vanadomolybdophosphoric acid method for phosphate evaluation exposed that 0.2% nano-chitosan produced the highest release of calcium and phosphate followed by 17% EDTA and pomegranate aril extract. Almost similar results were obtained in the studies done on permanent teeth by Pedro *et al.*^[2] However, contrast findings were seen in studies by Spanó *et al.*^[36] and Bastawy *et al.*^[9] in which 17% EDTA and 0.2% chitosan groups contained the highest concentration of calcium ions extracted from root canals, without significant difference between them. Nonetheless, study by Berastegui *et al.*^[37] exhibited the highest calcium loss from root dentin with EDTA than chitosan. The discrepancy in the results may be attributed to factors influencing the agents' demineralization capacity such as contact time, pH, concentration and the amount of available solution, assessment of calcium and phosphate ion concentration in the specimen rather than in solution, irrigation protocol followed coupled with difference in methodology.^[7] Furthermore, permanent dentin is richly mineralized, and concentration of calcium and phosphorus in both peritubular and intertubular dentin is also high. Even dentinal micromorphology studies showed potential differences between primary and permanent teeth.^[38]

It is believed that adsorption, ionic exchange, and chelation properties of chitosan are responsible for eliminating dentin calcium ions.^[39] There was a significant decrease in calcium and phosphate levels in dentin following EDTA treatment which was less than nano-chitosan. This might be attributed to the fact that EDTA forms a stable complex with dentin's calcium ions. Correspondingly, EDTA molecule's carboxyl groups ionize, releasing hydrogen atoms that compete with calcium ions. After all available ions are bound, equilibrium is formed, and no further dissolution occurs. It is also possible that dentin's organic matrix may act as a barrier in the dissolution of the inorganic component. Thus decalcifying action of EDTA stops.^[9] Pomegranate aril extract displayed least mineral loss, and possible reasons accredited to this may be weak organic acids such as ascorbic acid, citric acid, and malic acid in the arils, which have a weak chelating ability.^[28,40]

Notable variation in VHN values following irrigation protocol indicates the potential effect of these chemical solutions on radicular dentin components. The postimmersion VHN values in the present study suggest that dentin microhardness was significantly reduced by irrigating solutions compared to baseline values. As compared to pomegranate aril extract group, both 0.2% nano chitosan and 17% EDTA showed an identical reduction in root canal dentin's microhardness. The chelating activity of EDTA produces softening of calcified components of dentin, and subsequently, a reduction in the microhardness of the root canal dentin is noticed.^[29] The chelating property of chitosan responsible for calcium and phosphate extraction from radicular dentin might also be accountable for reduction in microhardness of dentin which was analogous with that of 17% EDTA. The results are in accordance with Pimenta *et al.*^[33] and Silva *et al.*^[34] who found that 0.2% chitosan is equally effective as 15% EDTA in microhardness reduction. On the other hand, Bastawy *et al.*^[9] reported that 0.2% chitosan caused less reduction in dentin microhardness than 17% EDTA. In case of pomegranate aril extract, it may be hypothesized that the presence of weak acids could have altered dentin's microstructure that is liable for a minimal reduction in root dentin VHN values. Nevertheless, it may be theorized that the time-dependent demineralization effect of the irrigation regimens tested herein may be reduced in the clinical settings by the presence of smear layer, volume of irrigant used, contact period, and irrigation protocol followed.

Conclusion

All the irrigants used in the study demonstrated mineral loss from the root canal dentin with maximum loss observed in 0.2% nanochitosan and least with pomegranate aril juice. A significant difference in the VHN values was recorded in all the tested groups,

suggesting that microhardness is directly proportional to mineral loss. Thus, the present study's observations demonstrate the need to incorporate herbal agents such as pomegranate extract as a valuable adjunct during endodontic procedures; however, further research to enhance its clinical applicability and establish its capability as a root canal irrigant needs to be evaluated.

ABSTRACT

Aim: The aim of the present study was to determine the remineralizing potentiality of artificial carious lesions in primary teeth after application of three commercially available dentifrices using pH cycling.

Materials and methods: A total of 24 human primary teeth were randomly divided into three groups. Group I: Clinpro Tooth Creme, Group II: Enafix, and Group III: Amflor. All the teeth in each group were demineralized for 96 hours, sectioned longitudinally using hard tissue microtome and subjected to pH cycling for 7 days. The specimens were viewed under polarized light microscope, depth of demineralization and remineralization was recorded using Micap Microview analyzer software.

Results: The results were analyzed using one way-ANOVA test. All the test groups showed statistically significant decrease in mean depth of lesion $21.62 \pm 9.41 \mu\text{m}$, $20.75 \pm 14.61 \mu\text{m}$, $26.13 \pm 17.84 \mu\text{m}$ for group I, II, and III, respectively. However, no statistical difference was noticed on intergroup comparison.

Conclusion: All the tested dentifrices demonstrated remineralizing potential which was elicited by decrease in the lesion depth. Amflor showed better results than other remineralizing agents.

Clinical significance: To emphasize the importance of minimal invasive treatment of incipient carious lesion by remineralizing agents. Opting for remineralizing agents at the early stage can save the time, money and manpower. Usage of dentifrices containing remineralizing agents shown long-term beneficial effects on early caries lesions. The present study demonstrated that all the tested agents can be used to induce remineralization of early enamel lesions, so that complex invasive treatments can be prevented in near future.

INTRODUCTION

Dental caries is the most prevalent oral disease and is considered as the major worldwide health concern. “White spot lesion” is the earliest clinical sign of dental caries.¹ In the recent decade, white spot lesions can be prevented through various noninvasive preventive modes, as the routine operative treatment is hard to achieve and may also need special behavior management for treating children.

In children, the demineralization potential at low oral pH is high while the remineralization potential at normal pH is low.² And also low mineral and high organic content of enamel made the primary teeth more susceptible to caries development. Hence, the progression of caries will be faster and reversal will be slower in children, as they depend upon the balance between demineralization and remineralization.³ Thus, in children while managing the initial caries lesions the most preferred noninvasive intervention is the usage of dentifrices containing remineralizing agents.

The ions liberated upon the application of remineralizing agents will act as diffusion barrier by the formation of thick surface coatings and also deposition of minerals within the enamel crystallites in turn decrease the solubility of enamel.⁴ Orientation of the remineralized enamel crystals is similar to that of the original enamel crystals and are generally more resistant to decalcification.

Fluoride’s role in remineralization is well established and effective method of remineralization. Fluoride containing dentifrices usually have a dose-response relationship; therefore dentifrices containing 250 to 500 ppm fluoride are used for children to reduce fluorosis risks. In accordance with IAPD Recommendations (2020), using fluoridated tooth paste containing 1000 ppm of fluoride twice a day with age-appropriate amounts of tooth paste on the toothbrush are effective in preventing dental caries in children.⁵

As science and research advances, newer fluoridated and nonfluoride remineralizing agents have been introduced in the market. The Clinpro Tooth Cremem contains functionalized tri-calcium phosphate ingredient (fTCP) with fluoride range of about 950 ppm. Each gram of it contains 0.95 mg of fluoride ion in a neutral pH base consisting of

water, hydrated silica, sorbitol, glycerin, polypropylene glycol, polyethylene-polypropylene glycol, flavor, sodium lauryl sulfate, titanium dioxide, carboxymethyl cellulose, and sodium saccharin.⁶ This organically modified TCP technology prevents undesirable reactions with fluoride, but may dissolve away when particles contact saliva. This system is stable in aqueous environment and does not affect the fluoride activity.⁷

Enafix contains anticay 5% which is a complex mix of calcium sucrose phosphate inorganic amorphous calcium phosphate, sorbitol, purified water, silica, glycerin, sodium lauryl sulphate, flavors, sodium methyl cocodyl taurate, sodium carboxy methyl cellulose, titanium dioxide, potassium acesulfame, sodium methyl hydroxyl benzoate, and sodium propyl hydroxyl benzoate. During brushing, calcium sucrose phosphate (anticay) quickly breaks down and releases calcium, phosphate, and sucrose phosphate ions into the saliva. Calcium and phosphate ions rapidly adsorb onto the enamel, decrease the rate of enamel solubility under acidic conditions and at neutral pH and increase the rate of remineralization.⁸

Amflor contains 1000 ppm amine fluoride, sorbitol, purified water, propylene glycol, silica, cocamidopropyl betaine, titanium dioxide, Hydroxyl ethyl cellulose and sodium saccharin. Amflor toothpaste contains the active ingredient in the form of amine fluoride (organic fluoride) which has caries inhibitory properties due to its antiglycolytic and surface-active properties. It also involves the accumulation of fluoride onto the surface of the tooth, which readily forms calcium fluoride and acts as a labile fluoride reservoir.^{8, 9}

These three remineralizing agents were chosen based on their difference in composition and also studies comparing the above forementioned dentifrices on the primary teeth are sparse. Therefore present in vitro study was undertaken to compare remineralization potential of three commercially available dentifrices (Clinpro Tooth Creme, Enafix, and Amflor) on artificial carious lesions.

MATERIALS AND METHODS

The present in vitro study was performed after obtaining institutional ethical committee approval (pr.171/IEC/SIBAR/2018). The sample size determination was done using G* 3.1.9.2; the effect size is 0.795 and sample size derived is 24. Teeth with preshedding mobility, natural exfoliation, extracted over-retained or orthodontic purpose were included. Whereas the teeth with cracks, white spots and dental caries, or any discolored teeth and hypoplastic teeth were excluded from the study.

Out of total 40 sound human caries-free primary teeth collected, 24 teeth, which fulfilled all the inclusion and exclusion criteria were selected for the study and stored in a 0.1% thymol solution until use.

Sample Preparation and Lesion Formation

The selected teeth were rinsed, hand scaled and thoroughly cleaned and dried. A rectangular window of 2 mm × 4 mm was labeled in the center of the buccal surface and the remaining surface of the tooth was coated with nail varnish. The teeth were randomly divided into three groups with 8 in each using computer randomization technique. The groups are as follows: Group-I: Clinpro Tooth Creme (3M ESPE Dental Products, St.Paul, MN, USA), Group-II: Enafix (Group pharmaceuticals pvt Ltd, Banglore, India), and Group-III: Amflor (Group pharmaceuticals pvt Ltd, Malar, India).

To create artificial caries lesions, all the specimens were immersed for 96 hours in a glass beaker containing 500 mL of demineralizing solution. With a diamond disk mounted on a slow-speed handpiece, the teeth are sectioned longitudinally in buccolingual direction. Each specimen shows a portion of the normal enamel and demineralized area. Out of two sections obtained from each tooth, one section was used to record depth of demineralization and other to record depth of remineralization.

The specimens used to record depth of demineralization in three groups were embedded in self cure acrylic (DPI- PR Cold Cure) resin blocks using a preformed mould. Later these specimens were sectioned using hard tissue microtome (Leica SP 1600 Saw Microtome, Germany) longitudinally through the lesions to produce sections of approximately 100 to 150 μm thickness to examine under polarized light microscope.

Recording the Demineralization Depth

The sectioned samples of each group were immersed in water for a clear demarcation between sound and carious enamel and then viewed under polarized light microscope (Olympus BX51 penta head microscope, Japan) at 40x magnification. After attaining the microscopic images (Fig. 1A, 2A, 3A), the depth of demineralization was noted at three different points from the surface of a tooth to the maximum depth of demineralization and the average of the three was considered as mean value (μm).

Figs 1A and B: (A) Polarized light microscopic image after demineralization in group I; (B) Polarized light microscopic image after remineralization in group I

Figs 2A and B: (A) Polarized light microscopic image after demineralization in group II; (B) Polarized light microscopic image after remineralization in group II

Figs 3A and B: (A) Polarized light microscopic image after demineralization in group III; (B) Polarized light microscopic image after remineralization in group III

pH Cycling

Ten Cate and Duijsters pH cycling model was used for all the samples after demineralization.¹⁰ It involved 3 hours of demineralization twice daily, with 2 hours of remineralization between periods of demineralization for 7 days. Each section was then treated with dentifrice supernatant for 60 seconds (5 mL/section).

The demineralizing, remineralizing solutions and dentifrice slurries were freshly prepared for each cycle and stored in separate containers for each group throughout the experimental period.¹¹ These solutions were changed daily to prevent depletion or saturation of the solutions and accumulation of enamel dissolution products.³

Recording Depth of Remineralization

Following pH cycling the specimens were embedded in acrylic blocks and sectioned using hard tissue microtome. Each section was visualized under polarized light microscope at 40X magnification to determine the amount of remineralization on microscopic images (1B, 2B, 3B) using Micaps-micro view 3.7 version software.

The entire procedure was performed by a single operator, however to avoid bias, a second operator who is unaware of prior results evaluated the procedural aspect and

recorded the values. intraclass correlation coefficient (ICC) values were calculated to examine the reliability. An intraclass correlation value of 0.93 was achieved which indicates good agreement among the investigators, hence the earlier observations were only taken into account.

RESULTS

The de- and remineralization values obtained were tabulated using SPSS and subjected to statistical analysis. Paired t-test was used to calculate mean lesion depth and standard deviations and one-way ANOVA for inter group comparison. The p -value of < 0.05 was considered statistically significant.

The mean lesion depth among the three test groups after demineralization ranged from 167.38 μm to 177 μm which was not statistically significant and after remineralization the values varied between 141.25 μm to 155.38 μm , which were also statistically insignificant. However, a decrease in the mean lesion depth was observed in the all test groups after remineralization.

Coming to reduction in mean lesion depth after remineralization Group III exhibited highest decrease in mean lesion depth (26.13 \pm 17.84 μm) followed by Group I (21.62 \pm 9.41 μm) and Group II (20.75 \pm 14.61 μm) samples. There was statistical significant decrease in mean lesion depth values in all the three groups after de- and remineralization for Group I, II, and III with a p -value of 0.001*, 0.005*, and 0.004*, respectively (Table 1).

Table 1: Comparison of mean lesion depth and difference in mean lesion depth before and after remineralization

Group	N	Mean \pm SD before remineralization	Mean \pm SD after remineralization	Mean difference	p value
I	8	177.00 \pm 11.88	155.38 \pm 16.37	21.62 \pm 9.41	0.001*
II	8	170.13 \pm 14.04	149.38 \pm 19.89	20.75 \pm 14.61	0.005*
III	8	167.38 \pm 16.02	141.25 \pm 24.4	26.13 \pm 17.84	0.004*

Paired t test; $p \leq 0.5$ considered statistically significant

DISCUSSION

Dr. L. KRISHNA PRASAD

Remineralization is a noninvasive treatment modality for the initial caries lesions that bridge the gap between preventive and invasive dentistry.⁸ Caries process is said to be dynamic when demineralization periods are far more than the periods of remineralization.¹ Saliva's inherent buffering capacity and the presence of calcium ions, phosphate ions, fluoride, and other components prevent the early tooth demineralization.¹² If this natural system of saliva fails, then remineralizing agents are needed to compensate the oral defensive mechanisms at that site and protect the tooth from cavitation. Thus, if remineralizing agents are used at this stage, caries can be arrested or reversed.¹³

In the present study, artificial carious lesions were produced as they are more homogeneously reproducible than natural lesions and showed all the principal histological features of natural caries of enamel *in vitro*.³ Extracted or naturally exfoliated primary teeth (molars, canines, and incisors) were used for lesion formation. Though there are variations in the morphology of individual teeth, it was hypothesized that these variations among the teeth do not have a significant role in caries formation.⁷

Single section model proposed by Wefel et al.¹⁴ was used for this study as it provides the advantage that the same tissue can be evaluated before and after the exposure period. Thus, any change could only be due to the exposure of the experimental solutions. Similarly, Kiranmayi et al.³ and Malekafzali et al.¹⁵ used single section pH cycling models for evaluating the efficacy of fluoride dentifrices on primary teeth.

Ten Cate and Duijsters pH cycling model can mimic the introral pH changes and results in more representative findings in evaluating remineralization efficacy of an agent.¹⁶ A 10-day pH-cycling model can be used on the enamel of permanent teeth whereas a 7-day pH cycling or 10-day cycling with added 0.25 ppm fluoride can be used for primary teeth.^{3,7} In the present study, 7 days pH cycling model without the addition of fluoride was used as incorporation of the same could interfere with the hypothesis being tested.

Polarized light microscope was used in the present study to assess the lesion depth of the artificial caries lesion for all specimens because the characteristic features of enamel can be better visualized due to its birefringence property, which is not well appreciated in a transmitted light microscope.¹⁷

The results of the present study quantified that all the tested groups showed better remineralization potential by decreasing the mean lesion depth. However, Group III elicited higher remineralization potential; which could be due to high fluoride content (1000 ppm) and the fluoride compound used (amine fluoride).

The results were similar to the studies conducted by Galuscan et al.¹⁸ and Madlena et al.¹⁹ who reported that amine (organic) component in amine fluoride (AmF) exhibited an antiplaque effect that resulted in the inhibition of bacterial adhesion. Also, the tensioactive

property of the amine component favors the accumulation of fluoride close to the tooth surface, providing a sustained fluoride release. Shetty et al.²⁰ also evaluated the enamel surface microhardness after the application of organic fluoride (AmF) and inorganic fluoride (NaF) dentifrices on permanent teeth and found AmF released a larger amount of fluoride than NaF, which caused the fluoride to be more bioavailable for a longer period of time. Likewise, Prasad et al.²¹ compared the remineralizing effect of organic fluoride (AmF) and inorganic fluoride (NaF) and found AmF showed better remineralization on the enamel surface of permanent teeth. This might be due to formation of a thick calcium fluoride layer between NaF (inorganic fluoride) and hydroxyapatite of enamel which inhibited the further diffusion of fluoride, thus providing a relatively lower bioavailability of fluoride ions. Arnold HW et al.²² Naumova EA et al.²³ also found that more amount of fluoride was deposited on enamel by treating with AmF than sodium fluoride which resulted in enhanced remineralization.

In this study group I (Clinpro Tooth Creme) showed a significant reduction in mean lesion depth thereby promoting remineralization. The reason may be due to the presence of a combination of sodium fluoride with functionalized tricalcium phosphate (f-TCP) which provides a continuous reservoir of ions. As it not only ensures a controlled supply of calcium and phosphate ions, but also enhances the action of fluoride on enamel surfaces. TCP can provide maximum advantages even when administered in a neutral pH environment, whereas other calcium phosphate additions may require an acidic pH.

In accordance to the present study, Rao R et al.²⁴ also found that ClinPro tooth Creme showed better remineralization potential and this could be due to beta-TCP is present in Clinpro tooth creme, which is similar in structure to apatite and has unique calcium environments capable of reacting with fluoride and enamel. While phosphate floats free, the exposed calcium environments are protected, preventing calcium from prematurely interacting with fluoride by providing catalytic amounts of calcium to boost fluoride absorption and promote remineralization.

Similarly, Krishnan et al.²⁵ found Clinpro as a promising agent for remineralizing primary teeth. Likewise, Sreekumar et al.,²⁶ Patil et al.¹ found that a higher concentration of calcium ion in f-TCP and addition of fluoride was responsible for its superior performance.

On Contrary, study done by Premanth et al.²⁷ found better remineralization with clinpro than Amflor in permanent teeth. This might be due to the synergistic effect of both fluoride compound (NaF) and functionalized tricalcium phosphate (f-TCP). The aqueous-stable functionalized calcium phosphate system has no effect on the fluoride activity added to dentifrices, which increases enamel surface strength. The available evidence, therefore indicated that TCP-containing dentifrices could remineralize teeth in a significant manner.

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

The significant reduction in mean lesion depth in group II samples could be due to rapid absorption of ions onto enamel surface, make the availability of the sucrose phosphate ion which decreases the rate of acid dissolution of hydroxyapatite that inhibits demineralization and presence of calcium and phosphate ions increase the rate of remineralization by common ion effect. Similarly, Gade²⁸ and George et al.²⁹ in their studies found Enafix as a favorable remineralizing agent for mineralization of artificially demineralized human enamel.

Although remineralizing ability of CaSP with inorganic ACP (Enafix) has shown promising results. However, in comparison to the dentifrices containing fTCP+NaF (Clinpro) and amine fluoride (Amflor), Enafix has shown less effectiveness in promoting remineralization in this study. This might be due to the nonavailability of fluoride ions, as soluble calcium and phosphates were unable to substantially localize at the tooth surface to produce effective concentration gradients for better remineralization. This concept was further supported by studies done by Titty et al.⁹ Kakkar et al.¹² in which Enafix formed a thick layer of calcium fluoride by reaction with hydroxyapatite of enamel that in turn reduced the bioavailability of fluoride ions.

Even though this *in vitro* experiment provides qualitative research, certain limitations do exist while performing remineralization in *in vitro* designs such as inadequate simulation of complex and diverse intraoral conditions, lower level of salivary proteins, lack of bacteria in the artificial saliva, control over the salivary flow rate, and lack of pellicle and biofilm formation on the tooth surface. Moreover the specimens were also exposed to multiple cycles of de- and remineralization, which may be severe than actual acid attack in the oral cavity. Hence, further studies need to be conducted with the forementioned points taking into consideration to obtain optimal clinical results.

CONCLUSION

All the three dentifrices used in the study demonstrated remineralization of artificial carious lesions. Among the three, amine fluoride containing dentifrice exhibited a superior remineralizing potential which might be due to the presence of high fluoride content and organic fluoride component (amine component). Also properties like antiglycolytic, tensioactive property, antiplaque, and anticariostatic effect are further considered for the beneficial effects of remineralization.

Background: Pain during fixed orthodontic treatment can have a detrimental effect on patient treatment compliance. To overcome this, there is a definite need to establish the best pain-relieving methods suitable for orthodontic patients in terms of efficacy and use. The objective of this study was to compare the effect of chewing gum and pre-emptive tenoxicam on pain after initial archwire placement and to evaluate the pain perceptions of orthodontic patients in the two groups while performing various functions at specific time intervals.

Methods: Forty-two patients were selected and randomly divided into two groups: group A (chewing gum) and group B (pre-emptive tenoxicam). Pain perception was documented by patients immediately; at 4 h; at bedtime on the day of archwire placement; the next morning; at 24 h; and at bedtime on the 2nd, 3rd, and 7th day after the initial archwire placement. Pain scores were noted during fitting of the posterior teeth, biting, and chewing using a visual analog scale. The data obtained were subjected to statistical analysis.

Results: Group A showed a significant increase in pain until the next morning while fitting the posterior teeth, biting, and chewing [36.2, 52.0, 33.4, respectively], followed by a gradual decrease by the 7th day. Group B showed a significant increase in pain at bedtime on biting, with a peak value of 47.5. Pain on chewing, fitting posterior teeth, peaked the morning of the next day (100.0, 45.0). The Friedman test showed a statistically significant difference with a p-value of < 0.01. Higher pain scores were observed while chewing and biting compared with that while fitting the posterior teeth in both groups. The overall comparison of pain control between the two groups was not statistically significant [P > 0.05] between the two groups.

Conclusions: Chewing gum was not inferior to pre-emptive tenoxicam. Thus, chewing gum is a non-pharmacological alternative to analgesics for orthodontic pain control that eliminates the chance of adverse reactions and can be used in the absence of adult observation.

Keywords: Chewing Gum; Orthodontic Treatment; Pain Control; Tenoxicam.

INTRODUCTION

Anxiety regarding pain and uneasiness during the

treatment phase is a concern for orthodontic patients. It is a crucial limiting factor for fixed-appliance therapy and may have a negative impact on patient compliance [1]. Soon after placement of the initial archwire, biological

variations occur in the periodontal ligament (PDL), resulting in the release of inflammatory mediators such as prostaglandins and bradykinin etc., [2] which mediate orthodontic pain [3,4]. Pulpal inflammation during fixed appliance therapy may also induce the pain [5,6]. The pain typically intensifies progressively after 2 h of applied orthodontic force, reaches a peak by 24 h, and gradually reduces by the seventh day [7-9].

To relieve pain and discomfort, clinicians employ either conventional pharmacological analgesic administration of nonsteroidal anti-inflammatory drugs (NSAIDs) or nonpharmacological methods. The latter includes the use of a plastic wafer [10], chewing gum [11,12], transcutaneous electrical nerve stimulation [13], low-level laser therapy [14,15], and vibratory stimulation [16].

Cheng et al. [17] revealed that preemptive analgesia is effective for orthodontic pain control. The mechanism involves the generation of analgesia prior to the induction of a pain stimulus, which may reduce pain intensity [18]. The inhibition of prostaglandin synthesis by NSAIDs also have adverse effects on tooth movement [19]. Tenoxicam (20 mg) was convenient for pain control without any impediments related to upper canine tooth movement [20]; hence, tenoxicam was used in the present study. Tenoxicam belongs to the oxycam group of non-selective COX inhibitors (NSAIDs) with a half-life of 67 h. It is beneficial in terms of usage to administer only a single dose of tenoxicam per day for orthodontic pain relief. In contrast, other non-selective COX inhibitors are prescribed three times a day, which increases drug intake.

The overuse and adverse reactions of NSAID challenge their use in contemporary analgesic management in adolescent patients [21,22]. Owing to these limitations, non-analgesic pain control methods have been approved [10]. Few studies have reported the efficacy of chewing gum for orthodontic pain control [23-25].

However, in a recent systematic review by Fleming et al. [26], very low-quality evidence was observed regarding pain relief with the use of chewing adjuncts. In this context, the present study aimed to compare the effectiveness of chewing gum and tenoxicam for pain

relief following initial archwire placement in patients receiving orthodontic treatment. To date, few randomized controlled trials (RCTs) have been included in systematic reviews on orthodontic pain management methods. To our knowledge, no RCTs has compared chewing gum and tenoxicam for pain relief in orthodontic treatment. Therefore, the present study aimed to compare the pain-relieving effect of chewing gum with that of pre-emptive tenoxicam.

METHODS

The present study was a uni-centered, two-arm parallel investigation approved by the Institutional Research Ethics Committee (University registration number: D168408007). One hundred twenty-one subjects requiring fixed orthodontic therapy were assessed for eligibility. Only female patients were included in the investigation to eliminate the influence of sex on the outcome assessment, as sex-dependent differences in pain perception have been reported [27].

Inclusion criteria: physically and mentally healthy women in the age group of 18–25 years, patients undergoing fixed orthodontic treatment for the first time, full arch bonding in both arches, extraction in both arches, and crowding with a minimal index of 4–9 mm.

Exclusion criteria: patients with systemic diseases, pregnant patients, patients in whom tenoxicam is contraindicated, patients under medication for chronic pain, and patients undergoing functional appliance therapy and orthognathic surgery.

A comprehensive medical history and informed consent were obtained.

Sample size determination: This was designed to preserve the power of the study at 0.8 (80%) and the level of significance at 0.05 (5%). [28] A total of 34 subjects were needed for the trial to detect a minimum difference of 10 mm on pain scale on visual analog scales (VAS) between any two subjects for any given function or time point. Considering a possible dropout rate of 20%,

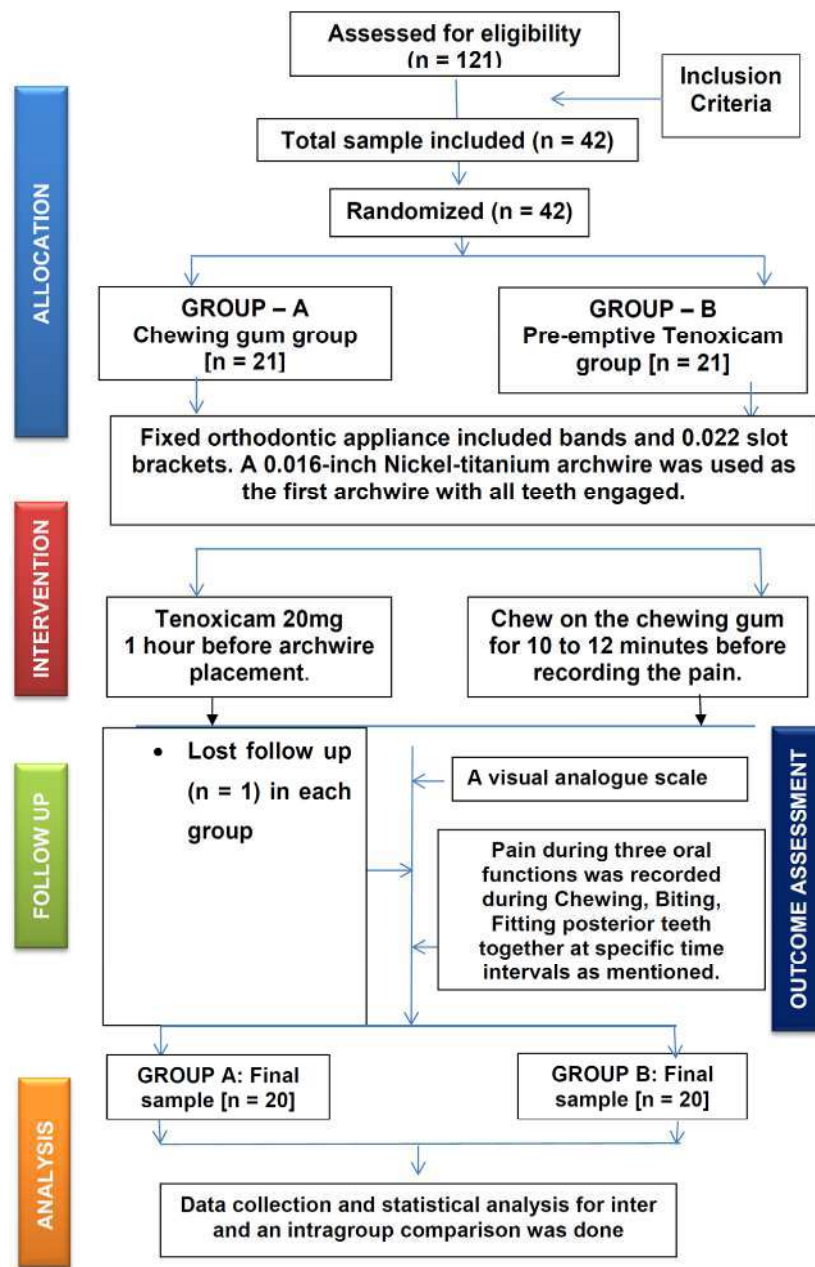

Fig. 1. Consolidated Standards of Reporting Trials flow diagram showing the study design.

a total of 42 female participants were selected for the trial and equally divided into two groups of 21 each.

Randomization: The patients were coded with a numerical value, and the data were entered into an Excel sheet and fed to a computer application. Simple randomization was performed using a 1:1 allocation. The sequences of the subjects assigned to the chewing gum group (group A) and the tenoxicam group (group B) were computer-generated with random numbers using a

research randomizer. Allocation was performed using opaque sealed envelopes. On the day of archwire placement, which was also the first day of the intervention, each subject chose one envelope to detect her randomized allocation.

Treatment: In both groups, orthodontic appliances included bands and 0.022 slot M.B.T brackets (3M Unitek™ Gemini Metal Brackets, USA). As an initial archwire, 0.016-inch nickel-titanium was placed. Patients

Table 1. Depiction of the differences in the demographic data between the 2 groups (Chewing gum and Tenoxicam group) (P-value > 0.05) is statistically insignificant

Demographic characteristic	Group	Number of participants	Mean \pm SD	P-value

in the chewing gum group were asked to chew on chewing gum (Trident, sugar-free gum with xylitol, U.S.A.) whenever they experienced discomfort. However, patients were advised to chew it for 10 to 12 min prior to pain recording at specific time intervals. In the tenoxicam group, the subjects took Tenoxicam B.P. (Tilkotil, 20 mg, Radiant Pharmaceuticals, Bangladesh.) 1 h before archwire placement. The work strategy was illustrated using a Consolidated Standards of Reporting Trials flowchart (Fig. 1).

Data collection: Subjects were given regular post-treatment guidelines and were suggested to fill out a feedback form at suitable intervals in the week after the bonding procedure. The questionnaire was given in a 7-page booklet containing a succession of 10 cm VAS, and each centimeter was divided into 10 mm. The patients were instructed to note the grade of pain experienced, from 0 to 100 (with 0 representing no pain and 100 representing severe pain), at the indicated time intervals, immediately after archwire placement (T_0), 4 h after archwire placement (T_1), at bedtime of the day of archwire placement (T_2), the next morning (T_3), at 24 h (T_4), and bedtime of the 2nd (T_5), 3rd (T_6), and 7th day after the engagement of the initial archwire (T_7).

The subjects were advised to record pain during three oral functions: fitting the posterior teeth together, chewing, and biting. To fit the posterior teeth, the subjects were instructed to fit the posterior teeth using a slight force. The patients used an almond for biting and chewing. They bit and chewed almonds and recorded their perceived pain.

Table 2. The Descriptive Data of the VAS scores for the 2 groups under study

Function	Time interval	Chewing gum	Tenoxicam
		Mean \pm SD	Mean \pm SD
Fitting posterior teeth	T_0	11.1 \pm 7.5	4.4 \pm 6.4
	T_1	16.7 \pm 5.35	16.2 \pm 6.01

analgesic used. Patients were requested to return to the completed pain diary at the next appointment.

Blinding: The clinician and patients were not blinded to the intervention because the usage instructions needed to be explained based on the intervention. However, the operator dealing with the feedback forms and the statistician evaluating the records were blinded to the intervention.

Outcome: Valuation of pain by patients using VAS at specific time intervals after initial archwire placement.

Statistical analysis: All statistical analyses were performed using SPSS Statistics for Windows software package, Version 21.0. (Armonk, NY: 2012). The histogram assessed the normal distribution of the sample variables and the results showed that the parameters were normally distributed. An unpaired t-test was used to demonstrate the differences in demographics between the two groups. The Friedman test was used to compare pain experienced at different points in time during the different functions within the group in both clusters. The Mann-Whitney U test was performed to determine pairwise comparisons between the two groups at different time

points for different functions and to assess the overall pain perception between the two groups.

RESULTS

Two patients, one in each group, discontinued participating in the study for personal reasons. Finally, the final sample size for statistical analysis was 20 participants in each study group. The demographic details of the study participants are presented in Table 1. The unpaired t-test revealed no significant differences in the mean age, height, and weight between the groups.

1. The course of post intervention pain

The descriptive data for the two groups displayed in Table 2 shows that the peak pain occurred at T3 in chewing gum group during biting and in the tenoxicam group during chewing. There was a slow decrease in T₇ pain in both groups. The pain experienced during biting or chewing was greater than that experienced while fitting posteriors in both groups.

Table 3. Comparison of Pain experienced at different points of time during the different functions in Chewing gum and Tenoxicam group- Friedman test (P-value = < .001)** is statistically significant

Function	Time intervals	Chewing gum group		Tenoxicam group	
		Friedman test value	P value	Friedman test value	P value
Fitting Posterior	T ₀ -T ₇	129.42	< 0.001**	129.956	< .001**
Biting	T ₀ -T ₇	133.66	< 0.001**	133.581	< .001**
Chewing	T ₀ -T ₇	123.10	< 0.001**	139.180	< .001**

Table 4. Pairwise comparisons of pain perceptions between the two groups at different points of time for different functions - Mann-Whitney test (P-value < 0.05)*, ** is statistically significant (P-value > 0.05) is statistically insignificant

Time intervals	Different functional activities		
	Mann-Whitney test P-value		
	Fitting posterior	Biting	Chewing
T ₀	< .001**	0.002*	< .001**
T ₁	0.577	0.532	< .001**
T ₂	0.227	0.002*	< .001**
T ₃	0.043*	0.023*	< .001**
T ₄	< .001**	0.174	< .001**
T ₅	< .001**	< .001**	0.849
T ₆	< .001**	0.633	< .001**
T ₇	< .001**	0.630	0.102

1) Chewing gum group

A significant increase in pain was observed until T₃ during fitting of the posterior teeth, biting, and chewing, followed by a gradual decrease by T₇ (Fig. 2A). The p-value was highly significant (P < 0.001) at all time points while performing various functional activities (Table 3).

2) Tenoxicam group

There was a significant increase in pain during biting at T₂. Pain on fitting the posterior teeth and chewing showed a peak value at T₃ (Fig. 2B). P-values indicated high significance (P < 0.001) at all the mentioned points of time while performing various functional activities (Table 3).

2. Comparison of VAS scores between two groups while performing various functions at different points of time

- The tenoxicam group showed less pain than the

chewing gum group during fitting of the posterior teeth at all times (Fig. 3A). In both groups, the pain increased until T₃ and gradually decreased by T₇.

- During biting, the tenoxicam group reported less pain, followed by the chewing gum group at all time points except T₂ (Fig. 3B). The tenoxicam group showed peak pain at T₂, whereas the chewing gum group showed peak pain at T₃.
- During chewing, patients in the chewing gum group reported less pain, followed by those in the tenoxicam group at all time points (Fig. 3C). Both groups showed an increase in pain until T₃ and a gradual decrease in pain by T₇.

3. Comparisons of pain perceptions between the two groups at different points of time for various functions (Table 4)

T₀, T₃: There was a statistically significant difference (P < 0.05) between the two groups in all functional activities.

T₁, T₂: There was a statistically significant difference (P < 0.05) between the two groups during chewing. However, statistical significance was not observed when fitting posterior teeth and biting.

T₄, T₆: There was a statistically significant difference (P < 0.05) between the two groups while performing all functional activities, except while biting, where there was no statistical significance.

T₅: There was a statistically significant difference (P < 0.05) between the two groups while performing all functional activities except chewing, which showed no statistical significance.

T₇: There was a statistically significant difference (P < 0.05) between the two groups while fitting posterior

teeth, whereas during chewing and biting, the difference was not statistically significant.

The Friedman test values of the two groups were similar during fitting posterior teeth and biting, whereas during chewing, the chewing group showed a lower value of pain (123.10) than the tenoxicam group (139.180), indicating that chewing gum is not inferior to tenoxicam in controlling orthodontic pain (Table 3). The overall comparison of tenoxicam and chewing gum revealed no significant difference ($P = 0.305$) between the groups.

DISCUSSION

Tenoxicam is a long-acting nonsteroidal anti-inflammatory agent that is effective in pain control. Its long-acting effect may be correlated with its high serum binding properties [29]. Previous investigations have focused on the efficacy of chewing gum for pain management [12]. Few studies have compared two analgesics [30], chewing gum, and short-acting NSAIDs [31] in regulating orthodontic pain. No study has compared the efficacy of chewing gum with that of long-acting NSAIDs for pain reduction during orthodontic therapy.

Therefore, this work aimed to compare the effects of chewing gum and pre-emptive tenoxicam on pain perception once initial archwire engagement was done. In this study, the present pain levels for both groups followed a similar curve. In both groups, the intensity of pain during various functions gradually increased from T_0 , reached its extreme intensity at T_2 and T_3 and gradually decreased by T_7 . This outcome was supported by the observations of Law et al. [32], Polat et al. [33], and Jones and Chan [34]. They established that the pain was maximum in the morning after initiating treatment, with uneasiness progressively declining by day 6.

Fixed appliance therapy results in variations in the vascular supply. This occurs because of the sensitization of different proprioception centers by prostaglandins, glutamate, and gamma-aminobutyric acid [35,36]. The

prostaglandin production reaches a maximum level by 24 h and then decreases in the next 7 to 14 days [37]. Similarly, the increased production of neuropeptides resulting in antidromic inducement of afferent nerve terminals leads to pain. The increased levels of inflammatory mediators could be the reason for the pain experienced by patients after archwire insertion in the present study.

Factors such as the amount of orthodontic force applied to dentoalveolar structures and the severity of crowding do not play a key role in the patient's distress. Evidence regarding the impact of patients' age on pain perception after treatment is unpredictable [38]. To avoid the impact of age on outcome assessment, the current study was limited to 18–25-year age clusters.

To date, investigations related to the use of NSAIDs as pre-emptive analgesic for orthodontic pain control have been successful [30]. According to Davidovitch and Shanfield [37], NSAIDs are the gold standard for pain regulation during orthodontic treatment. According to Law et al. [32], usage of ibuprofen prior to orthodontic therapy shows positive discrimination towards orthodontic pain control. Pre-emptive analgesia works by blocking afferent nerve impulses in advance; therefore, there is no central sensitization of the nervous system. Administration of NSAIDs prior to the initiation of treatment facilitates biotransformation of the drug and further helps minimize inflammation and tissue trauma [33].

The use of certain agents that might momentarily move the teeth and adjacent tissues during orthodontic treatment will aid in the resolution of inflammation, thereby decreasing pain. Based on this conviction, Proffit and Fields [38] suggested chewing gum for orthodontic pain management. Patients often request a substitute pharmacological approach for pain management. Chewing gum is the best alternative because it is economical and safe to use. Therefore, in this study, chewing gum was compared with tenoxicam.

The recorded pain scores were higher while biting and chewing than while fitting posterior teeth in both groups. This could be attributed to the fact that the teeth are in

maximum intercuspation position during biting and chewing. This concurs with the findings of Polat [33]. Both tenoxicam and chewing gum were effective in fitting posterior teeth and biting. Chewing gum helps loosen the firmly arranged PDL fibers around the neurovascular bundles, repairing the regular flow of the lymphoid and circulatory system of the PDL, consequently eliminating inflammation and edema, and finally reducing pain and distress. This might have contributed to the effective pain control in the chewing gum group during chewing. Alshammari et al. [39] also reported the effectiveness of chewing gum as equivalent to paracetamol after initial archwire placement. Silva et al. [40] advocated chewing gum as a non-pharmacological alternative to acetaminophen and ibuprofen. The overall pain perception among the chewing gum and tenoxicam clusters was similar and not statistically significant. Hence, chewing gum might be an alternative to preemptive tenoxicam. The findings of our study were similar to those of Ireland AJ [31].

The limitations of the current study are that it was a unicentric study, and the sample size was small. Another limitation is the possibility of bias during the study, because the previous VAS scores noted by the participants may have influenced the subsequent pain scores. To minimize this, each VAS score was recorded on a new page in the booklet. There is a definite need to perform evidence-based research, including multicenter randomized clinical trials with a larger sample size to formulate a standard protocol for pain management by comparing various non-pharmacological options with long-acting NSAIDs during fixed orthodontic treatment.

In conclusion, the intensity of pain during various functions gradually increased after initial archwire placement, reached its extreme by the next morning or within 24 h, and then gradually decreased by the seventh day in both groups. Pain experienced during biting or chewing was significantly greater than that experienced while fitting posterior teeth. Chewing gum was not inferior to pre-emptive tenoxicam. Thus, chewing gum is a non-pharmacological alternative to analgesics for

orthodontic pain control that eliminates the chance of adverse reactions and can be used in the absence of adult observation.

Driftodontics

Physiological drift

Crowding

Extraction

ABSTRACT

In spite of the tremendous improvements in technology that allow for fewer patients to require extractions, there are always patients who have significant enough crowding that ultimately necessitate the removal of premolars.

Alleviating the lower anterior crowding prior to placement of the fixed appliances shortens the time in braces, and allows self correction by natural drift. One such treatment strategy which allows all this is Driftodontics.

This paper is intended to bring forth the clinical advantages of driftodontics by showing some of our cases which achieved efficient results.

1. Introduction

Space gaining methods in orthodontic treatment of crowded teeth include expansion, distalization, proximal slicing or extraction of teeth. Cases which necessitate extraction of teeth should be critically evaluated, for selection of teeth to be extracted and time of extraction to avoid undesirable tooth movement into extraction space.¹ As physiological drift of the teeth is most often in the mesial direction because of mesial component of force, greater mesial movement of molars is seen with second premolar extraction than first premolar extraction.² However, teeth mesial to the extraction space move in distal direction.

Potential benefits from a period of physiologic dental drift post-extraction, was proposed by Bourdet.³ “Driftodontics” is a term that can be attributed to Dr. R.G. “Wick” Alexander in his textbook.⁴ The benefits include shorter period of fixed appliance therapy because of unprompted alignment of the teeth, oral hygiene problems due to appliance therapy decreases because of less time

period of appliance in the oral cavity and the dentoalveolar support also increases.^{5,6}

2. Case Reports

2.1. Case 1

An 18-years old female patient presented with a chief complaint of forwardly placed upper front teeth. Clinical examination revealed convex profile with competent lips, Angles class I malocclusion with crowding in the lower anterior region, skeletal class I with normodivergent growth pattern, proclined upper and lower anteriors (Figure 1). Based on clinical and cephalometric findings we have planned for all 4's extractions and driftodontics in the lower arch. Immediately after the extractions, banding and bonding of upper arch was done with 0.022 MBT bracket prescription. Initial alignment of upper arch was done with 0.016 inch, 16x22inch and 19x25inch NiTi wires. After 4 months of upper arch strap up, lower arch was bonded and aligned (Figure 2). Space closure was done using 19x25SS wire.

2.2. Case 2

A 13 year old male patient reported with a chief complaint of irregularly placed teeth. Initial examination revealed convex profile with incompetent lips, Angles class I malocclusion with crowding in the upper and lower anterior region, cross bite in relation to 26, lower midline shifted to right by 3mm. Skeletal class I with normodivergent growth pattern and proclined upper incisors (Figure 3). Due to excessive crowding in the upper and lower arches, we decided to treat the case by extracting upper and lower first premolars. After the extractions, banding and bonding of upper arch was done with 0.022 in MBT bracket prescription. Expanded transpalatal arch was placed between 16, 26. Initial alignment of upper arch was done with NiTi wires sequentially starting from 0.014 inch wires. Lower arch was left for driftodontics for 5 months in this case, later on bonding was done and aligned (Figure 4).

Fig. 1: Pretreatment intraoral and extraoral photographs for case 1

Fig. 2: Series of lower occlusal photographs showing driftodontics over a period of 4 months (A-D) for case 1

2.3. Case 3

A 17-year-old female patient came with chief complaint of irregularly placed teeth. The patient was mesoprosopic and had convex profile with competent lips. Skeletal class I with normodivergent growth pattern and proclined upper incisors. Intraoral examination revealed Angles class I malocclusion with crowding in the upper and lower anterior region, cross bite in relation to 22,25, lower midline shifted to right by 2mm. (Figure 5). Extraction of all 4's done followed by banding and bonding of upper arch with 0.022 in MBT bracket prescription. Anterior bite plate was inserted to correct the crossbite. Initial alignment of upper

Fig. 3: Pretreatment intraoral and extraoral photographs for case 2

Fig. 4: Series of lower occlusal photographs showing driftodontics over a period of 5 months (A-D) for case 2

arch was done with 0.014 inch followed by 0.016 inch, 16x22inch and 19x25inch NiTi wires. In a period of 3 months significant amount of crowding was relieved in the lower arch (Figure 6). After 3 months of driftodontics in the lower arch, strap up was done and aligned.

Fig. 5: Pretreatment intraoral and extraoral photographs for case 3

3. Discussion

In orthodontics, treatment plan for cases with severe crowding usually include extraction of premolars and immediately banding and bonding of upper and lower arches. In contrast, driftodontics encourage delayed lower arch bonding to allow physiological drift of canines distally into first premolar extraction spaces which will create space for the anterior teeth to relieve crowding.

In his study^{2,4} Papandreas showed that when the maxillary arch is treated and the mandibular arch is allowed to drift for 6 months, predictable movements will take place:

1. Canines will drift distally
2. Incisors will upright
3. Anterior crowding will diminish
4. Molars will drift mesially, but only slightly

Weber⁷ showed that approximately one third of the space closure following first premolar extraction is taken up by mesial molar movement, two thirds is accounted for distal canine movement. Berg and Gebauer⁸ attributed 80% of the space reduction to distal drifting of the canines.

Mandibular molars will be in relatively in more stable position.² In critical anchorage cases lower lingual arch can be placed to prevent lower molar mesial movement which accounts for use of total extraction space for decrowding of anteriors.

Driftodontics will be most successful, if there is minimal skeletal discrepancy and an average overbite. Drifting of crowded canines distally will be more influenced by the lip and tongue muscle action.⁹ So we had chosen cases with skeletal class I, Class I molar relation with crowding in the lower anterior region, matching soft tissue with competent to potentially competent lips.

This physiological drift will be more only in first six months after extractions,² so we have observed changes in the present cases in a period of 4, 5 and 3 months respectively.

Bonding of crowded teeth will be much difficult. Aligning of severely rotated teeth eventually needs change in the bracket position after derotation which will consume much time because the orthodontist again has to go for undersized wires. Complicated mechanics or multilooped arch wires are needed to correct severe crowding which will be difficult for the patient to maintain oral hygiene and which leads to fewer emergency appointments and most importantly happier patients. Hence, extracting and allowing teeth to drift makes bonding easier, will simplify treatment mechanics and reduce the chair side time and overall treatment time.

The other advantage of driftodontics is in case of instanding lower incisors. Placement of continuous archwire in these cases will lead to movement of roots further linguallly. Driftodontics will help in this situation to achieve much better result in lesser time by natural drift into the

extraction spaces.

Generally in driftodontics cases, upper arch aligning and levelling, retraction will be carried simultaneously so that any kind of occlusal interferences for lower canines to move distally will be reduced.

As second and third cases had Class I molar relation with single tooth crossbites, anterior bite plate was used to avoid occlusal interferences effect on the changes in position of lower canines. Most of the lower anterior crowding was relieved by distalization of anteriors into extraction space within 3-5 months.

4. Summary

Alleviating the lower anterior crowding prior to placement of the fixed appliances will have advantages like

1. Shortens the time in braces, which leads to fewer emergency appointments
2. Avoid movement of roots of blocked out incisors further linguallly
3. Avoid complicated mechanics and multilooped archwires
4. Placement of bracket in correct position
5. Better anchorage control
6. Better oral hygiene,

5. Conclusion

As said by Creekmore, "Sometimes doing nothing is doing something".¹⁰ Sometimes letting teeth move in a physiologic way is better than moving them by orthodontic force. Proper case selection and less traumatic extraction of premolars play an important role in the success of driftodontics cases.

Abstract

Aim: The aim of the study was to compare and evaluate the microleakage under the Adhesive Precoated Plus (APCP), APC Flash-Free (APCF), and conventional stainless steel (SLS) brackets on the occlusal and gingival sides of the bracket base.

Materials and Methods: 66 extracted premolar teeth were collected and divided equally into 3 groups. Bonding was done with APCP, APCF, and conventional SLS brackets using Transbond XT. After bonding, the samples were stored in a distilled water and thermocycled for 3000 cycles, followed by immersion in a 2% methylene blue for 24 h. After cleaning, the teeth were mounted in acrylic and sectioned longitudinally at about the center of the bracket in a buccolingual direction. Microleakage was recorded using a stereomicroscope.

Results: Kruskal–Wallis H test showed a significant difference ($P < .005$) in the microleakage scores between the 3 groups. Mann–Whitney U test showed a significant difference between group 1 to group 2 and group 1 to group 3 ($P < .005$) and an insignificant difference between group 2 and group 3 on the occlusal side ($P = .116$) and on the gingival side ($P = .063$).

Conclusion: Conventional SLS bracket group exhibited greater microleakage scores at both occlusal and gingival sides, when compared with APCP and APCF groups.

Keywords

APC plus, APC Flash-Free, microleakage, stainless steel brackets

Introduction

The introduction of the direct bonding technique in orthodontics by Buonocore¹ in 1955 revolutionized orthodontic therapy. Bracket bonding with light-cured composite has become increasingly popular in orthodontics because of longer material working time and flexibility in initiating the polymerization process, which means “on-demand polymerization.”² In 1992, a new-generation bracket system called adhesive precoated (APC) brackets were introduced. Each bracket is individually packaged, and the bracket bases are prepaste with the optimal amount of adhesives.^{3,4} According to Cooper et al,⁵ APC offers some advantages over the conventional system, such as consistent quality and quantity of adhesive, easy debonding, reduced adhesive wastage, improved asepsis, and better inventory control. The Adhesive Precoated Plus (APCP) system has provided better tolerance to humidity and has a fluoride-releasing effect. The adhesive's color change property helps the

practitioner clean up the flash by providing a visual marker of adhesive placement. Conventionally, the flash needs to be removed before polymerizing the adhesive to avoid gingival irritation and plaque accumulation.⁶

Studies aimed to reduce the excessive flash adhesive led to the development of different systems. The APC Flash-Free adhesive coated (APCF) appliance system developed by 3M Unitek (Monrovia, California, USA) uses individually packaged brackets with a low viscosity resin, applied to a

nonwoven polypropylene mesh, which eliminates the need for flash removal and creates a seal to reduce microleakage.⁷ Microleakage is an essential drawback of orthodontic adhesives because of photopolymerization shrinkage of the adhesive during curing. The shrinkage creates a gap between adhesive and enamel surface, allowing the infiltration of bacteria, fluids, and ions from the oral cavity. In addition to polymerization shrinkage, thermal stresses to the adhesive in the oral cavity would cause the adhesive joint's fatigue, causing microleakage. Microleakage can lead to white spot lesions under and surrounding the brackets and reduce the bond strength at the enamel-adhesive-bracket interface.^{8,9}

Previous studies^{10,11} have shown increased microleakage at the enamel-adhesive interface rather than at the bracket-adhesive interface. Arhun et al⁹ showed increased microleakage with metal brackets compared to ceramic brackets and on the brackets gingival side compared to the occlusal side. Kim et al⁷ compared microleakage under APCP and APCF ceramic brackets and reported no significant difference between the systems in the extent of microleakage.

However, comparative studies reflecting the extent of microleakage under conventional metal brackets, APCP metal brackets, and APCF metal brackets are scanty. Hence, the present study has been taken up to assess the microleakage under APCF metal orthodontic brackets from gingival and occlusal surfaces at the enamel-composite interface and compare that with conventional metal brackets bonded with conventional composite adhesive and with APCP metal brackets.

Materials and Methodology

66 freshly extracted premolar teeth were collected. The sample size was determined using G*power version 3.1.9.2 (SPSS VERSION 14(SPSS Inc., Chicago, Illinois, USA)) with a confidence interval of 95%, power of 80%, $\alpha = 0.05$, and effect size of 0.40. The sample included in this study was teeth with intact buccal enamel, teeth that were not subject to any pretreatment chemical agents (such as hydrogen peroxide), teeth having no cracks, no caries, and no previous orthodontic bonding. Teeth were stored in 0.1% thymol to inhibit bacterial growth. All samples were cleaned and polished with pumice and rubber prophylactic cups for 10 s and consequently etched with 37% phosphoric acid (D-tech dental technologies, Wagoli, Pune, India) for 15 s and then rinsed with water and air-dried to see the white frosty appearance of etched enamel. Teeth were divided into 3 groups: group 1 bonded with conventional metal brackets with conventional composite, group 2 with APCP metal brackets, and group 3 with APCF metal brackets. Each group consisted of 22 samples.

Group 1: Prepared samples from group 1 (22 premolars) were taken, and a thin layer of Transbond XT primer was applied onto the enamel surfaces, and a gentle burst of air was applied to uniformly spread the primer. The Transbond XT (3M Unitek, Monrovia, California, USA) adhesive composite

was placed on the conventional stainless steel (SLS) bracket (3M Unitek) bonding surface, and then it was placed in the middle of the crown on the labial surface. The gentle force was applied to squeeze out the excess resin, which was removed using an explorer without disturbing the bracket.

Group 2: Prepared samples from group 2 (22 premolars) were taken, and a thin layer of Transbond XT primer was applied to the enamel surfaces, and a gentle burst of air was applied to uniformly spread the primer. APCP adhesive system brackets were placed on the middle of the crown on the labial surface. The gentle force was applied to squeeze out the excess resin, which was removed using an explorer without disturbing the bracket.

Group 3: Prepared samples from group 3 (22 premolars) were taken, and a thin layer of Transbond XT primer was applied to the enamel surfaces, and a gentle burst of air was applied to uniformly spread the primer. APCF adhesive system brackets were placed in the middle of the crown on the labial surface. All the adhesives were cured with light emitting diode (LED) with a wavelength between 450 nm and 470 nm and at an intensity of 1100 mW/cm² for a total of 20 s (10 s each on the mesial and distal sides).

To ensure complete polymerization of the bonding materials, all the teeth were stored in distilled water bath at 37°C for 24 h. All teeth were thermocycled for 3000 cycles between 5°C and 50°C. During the thermocycling procedure, all the teeth were exposed to 8°C for 30 s, followed by normal room temperature for 30 s and later to 45°C for 30 s. After the thermocycling procedure, roots of all teeth were sectioned 5 mm from the cervical margins, and exposed root canals were blocked with sticky wax. All teeth surface except 1 mm around bracket bases were coated with 3 different color varnishes to differentiate various groups (group 1 with red, group 2 with green, and group 3 with brown).

Microleakage Evaluation

All the teeth were immersed in 2% methylene blue for 24 h. The teeth were then thoroughly cleaned and brushed around the brackets to remove any excess dye and stains. All the teeth were embedded in cold cure acrylic blocks taking care to keep the brackets' center in line with the long axis of the

Figure 1. Teeth Sectioned in a Buccolingual Direction Through the Center of the Bracket.

Figure 2. Sample Showing Microleakage at the Occlusal and Gingival Border of the Bracket Base.

acrylic blocks. Teeth were sectioned longitudinally through the center of the bracket, using diamond cutting equipment, and cut surfaces were thoroughly polished (Figure 1). Microleakage was recorded using a stereomicroscope with MICAPS-microview software on the occlusal and gingival regions of the brackets at the tooth adhesive interface (Figure 2). Half of the samples were randomly selected and examined again by the same observer after 2 weeks to measure the intraobserver error of measurements.

Statistical Analysis

Statistical analysis was performed using Kruskal–Wallis H tests to test the difference between the groups and Mann–Whitney U test to compare the differences between 2 independent groups. The level of statistical significance was set at $P < .005$. Intraobserver error was evaluated with the Kappa statistics.

Results

The mean intraobserver agreement was acceptable ($\kappa = 0.64$). Mean microleakage scores measured at the occlusal side of the

bracket in the conventional SLS group are 0.106 ± 0.005 mm and on the gingival side are 0.349 ± 0.015 mm. In the APCP group, the measured mean scores on the occlusal side is 0.057 ± 0.004 mm, and on the gingival side, it is 0.104 ± 0.006 mm. In the APCF group, the measured mean scores on the occlusal side are 0.052 ± 0.004 mm and 0.088 ± 0.007 mm on the gingival side (Table 1). The conventional SLS bracket group exhibited more microleakage than the APCP group and APCF group, both on the gingival and occlusal side of the brackets.

Higher microleakage scores were observed on the gingival side of the bracket than on the occlusal side in all the 3 groups and the difference was statistically significant ($P < .005$; Table 2; Figure 3).

Kruskal–Wallis H test showed a significant difference ($P < .005$) in the microleakage scores on the occlusal side and

gingival side between the 3 groups (Table 3). While the Mann–Whitney U test comparison between independent groups showed a significant difference between conventional SLS–APCP and conventional SLS–APCF groups ($P < .005$) and an insignificant difference between APCP and APCF groups on the occlusal side ($P = .116$) and on the gingival side ($P = .063$; Table 4).

Discussion

Microleakage from an orthodontic point of view is the seeping and leaking of fluids and bacteria between the enamel–adhesive or adhesive–bracket interface. Polymerization shrinkage of the adhesive and differences in the rates of thermal expansion and contraction between the adhesive, bracket, and the enamel during exposure to hot and cold foods can cause gaps between the adhesive and enamel or between the adhesive and the bracket thus contributing to microleakage.

Microleakage presents the likelihood of formation of white spot lesions on the enamel at the adhesive–enamel interface and a reduction in the shear bond strength of the adhesive leading to bracket failure. It is reported that an average of 2 of the 3 teeth bonded with an orthodontic adhesive were affected

by some form of enamel opacity after orthodontic treatment; the most common type identified as diffuse opacity. O'Reilly and Featherstone¹² and Øgaard¹³ have shown that visible white lesions can develop within 4 weeks. Although microleakage-oriented caries is a well-documented entity in the restorative dentistry literature, the potential of caries adjacent to and beneath orthodontic brackets as a result of microleakage remains an underestimated threat to the permanent tooth, especially concerning long-term fixed appliance therapy. Several techniques have been introduced to assess microleakage around dental restorations. Microleakage is determined by a variety of in vitro techniques such as air pressure, fluid filtration, dye penetration, and microcomputed tomography^{14–16} and the most commonly used evaluation method is that of dye penetration.^{14,17,18} Researchers use colored dye agents or chemical tracers, which can penetrate and stain. The specimens are then sectioned longitudinally through the research area and assessed with stereo optical microscopy or scanning electron microscopy. To evaluate the relevance of a leakage test, the effective size of oral bacteria must be considered. Because of the range of bacteria sizes, dyes such as methylene blue and fuchsin are realistic agents to identify the presence of a clinically relevant gap.^{19,20} 2% methylene blue dye penetration was chosen for this study for the assessment of microleakage at the enamel–adhesive interface on the occlusal and gingival sides of the bracket. Thermal cycles were used in this study to mimic thermal changes in the mouth for the production of thermal stress at the tooth–adhesive interface.

The procedure of bonding orthodontic brackets at the enamel surface with composite resin consists a series of preparatory steps. New orthodontic materials are getting evolved in an effort to reduce the procedure time without reducing the bond strength of the bracket. APC brackets, a new generation bracket system introduced in 1992, had bracket bases prepaste with the optimal amount of adhesives. The APCP system provided better tolerance to humidity, has a fluoride-releasing adhesive, and the color change property of the adhesive helps to practitioner clean up the flash by providing a visual marker of adhesive placement. Excess flash is removed before curing an orthodontic bracket to avoid gingival irritation and plaque accumulation. Efforts aimed at reducing the excessive flash led to the development of APCF bracket systems. When APCF brackets are pressed on the enamel surface, the adhesive resin spreads out and conforms to the surface and creates a channeling border at the edges of the brackets, thus creating a seal to reduce microleakage.

This study evaluated and compared the microleakage scores at the enamel–adhesive interface on the occlusal and gingival side in conventional SLS, APCP, and APCF brackets. The mean of the microleakage scores both at the gingival and occlusal sides of the bracket was significantly lesser in APCP and APCF compared to conventional metal brackets. However, although the scores were higher on the gingival and occlusal sides of the bracket in APCP over APCF, the difference was insignificant.

The mean microleakage scores with metal brackets in the current study were in the ranges reported by Ulker et al²¹ and James et al,²² but were lesser than the mean values reported in the study by Abdelnaby and Al-Wakeel,⁸ In the present study LED light was used to bond the metal brackets, while James et al in their study used halogen light, argon laser, and plasma arc curing light. The results of the present study support the results of Ulker et al²¹ who concluded that the type of light-curing unit has an insignificant influence on the microleakage scores. Microleakage scores were measured at the gingival and occlusal sides of the bracket in the present study, while James et al in their study measured at the bracket margins after debonding the bracket. Abdelnaby and Al-Wakeel⁸ measured microleakage at the underneath the bracket base after debonding.

Significantly lesser microleakage scores with APCP and APCF brackets are consistent with studies that show that the filler content of the adhesive has an inverse relation to the polymerization shrinkage. Decreased filler content causes greater polymerization shrinkage.²³ Transbond XT has approximately 3% lesser filler content than the APCP, and this could have contributed to lesser microleakage with APCP brackets. The APCF system has a nonwoven mat at the bracket base, saturated with resin adhesive. When pressed on the enamel surface, the transparent resin forms a channeling border at the edges of the brackets, thus sealing the bracket on the margins. The superior performance of APCF brackets over APCP brackets is consistent with the findings of Foersch et al,²⁴ which reports dye penetration in 35% of interfaces with APCF brackets relative to 97.5% of interfaces in APCP brackets. The results of the present study are consistent with the findings of Lee and Kanavakis⁴ that proved the APCF system showed increased shear bond strength compared with the APCP system and shear bond strength is an absolute indicator of gaps and microleakage in the adhesive. However, microleakage scores with APCP metal brackets in the present study were significantly lesser than the values reported by James et al²² in those brackets cured by argon laser and halogen light but were comparable to the values obtained with plasma arc curing.

Mean microleakage scores in all the 3 systems of stainless-steel brackets were higher at both occlusal and gingival side of the bracket than the scores with conventional, APCP, and APCF ceramic bracket systems reported in the previous studies.^{7,25} A possible explanation for this finding is the “incomplete polymerization” phenomenon. In restorative dentistry, researchers have documented several factors that affect the depth of photoactivated cures, including duration and intensity of light exposure, filler type and shade of adhesive resin, and the reflective characteristics of the adhesive resin bulk.²⁶⁻²⁸ As light passes through the bulk of the restorative resin material, its intensity decreases greatly, thus decreasing the potential for cure. This decrease results in a gradation of the cure such that it decreases from the top surface inwards.²⁹ In orthodontics, brackets may act as the

bulk of restorative material. Because metal brackets do not conduct light, the underlying adhesive resin may remain incompletely polymerized. Several studies have shown that ceramic brackets produce significantly stronger bond strength compared with conventional metal brackets.³⁰⁻³² Increased bond strength with ceramic brackets resulted in bond failure at the enamel surface rather than at the bracket–adhesive interface, resulting in more enamel fractures after debonding.^{23,32-34} This increased strength and difficulty in debonding for ceramic brackets may be attributed to the close adhesion of the ceramic bracket to the adhesive in the absence of microleakage. Similarly, the weaker bond strength of metal brackets may be attributed to relatively more microleakage between the bracket and the adhesive.

In the present study, microleakage was significantly greater on the gingival side than on the occlusal side. In the present study, the curing device was used from both sides for equal time duration. However, the difference in the microleakage scores could be explained by the fact that a greater surface curvature anatomy at the gingival side may result in a thicker adhesive at the gingival margin. The results of the present study are consistent with the previous studies^{9,13,35} which report increased microleakage at the gingival margin than on the occlusal margin.

In restorative dentistry, the shrinkage of the resin caused by the rapid curing with high-intensity lights has been considered a disadvantage because of the large amount of resin placed in the cavity. Fast curing may generate excess shrinkage by permitting little opportunity for the flow of cured resin; also, it may result in gap formation along the resin–tooth interface, which most likely increases the potential for microleakage. However, from an orthodontic perspective, this condition is different. Adhesives at the edges of the bracket can absorb some shrinkage,⁹ and this shrinkage can pull the bracket closer to the enamel by the bracket's free floating. In contrast to the thick composite resin put in the prepared cavity in restorative dentistry, polymerization shrinkage and the subsequent microleakage is less of a concern in orthodontic adhesives because only a thin layer is used.

In the present study, APCP and APCF groups were cured with the LED light-curing unit, etched with 37% phosphoric acid, and microleakage was observed at enamel–adhesive interface only. However, the compatibility of APCP, APCF bracket systems with various curing methods such as plasma arc, argon laser, and halogen light curing and with various methods of enamel surface preparation such as self-etching primers, Er:YAG laser, and Er, Cr:YAG laser could significantly influence the level of microleakage between enamel–adhesive–bracket interface.

Future studies are recommended to test in vivo properties of the APC and APCF systems as well as the compatibility of the above systems to various curing and enamel preparation methods at both enamel–adhesive and adhesive–bracket surfaces.

Conclusion

1. Microleakage was observed in all the investigated groups.
2. The conventional SLS bracket group exhibited higher microleakage scores compared with APCP and APCF bracket systems at both occlusal and gingival sides.
3. Gingival sides in all groups exhibited higher microleakage scores compared with those observed in occlusal sides for the enamel–adhesive interface.
4. APCP and APCF bracket systems do not have a significant difference in the microleakage levels at the enamel–adhesive interface.

Evaluation of Dimensionality and Reliability of the Autonomy over Smoking Scale among South Indian Smokers

Abstract

Introduction: In spite of the efforts being directed at reducing the tobacco use among public, it remains a significant concern facing India today. In the quest of providing tobacco cessation counseling, documentation of the tobacco dependence of the individuals is quintessential. This study aims to assess the psychometric properties of the autonomy over smoking scale (AUTOS) among patients seeking oral health care at a teaching dental institution in southern India. **Materials and Methods:** The study sample constituted 199 subjects who satisfied the eligibility criteria of self-reported current smoking and were willing to participate in the study. Participants' age, gender, and years of smoking were documented along with their nicotine dependence by administration of Fagerstrom test for nicotine dependence (FTND) and AUTOS by a trained interviewer. The dimensionality of AUTOS was verified by confirmatory factor analysis using the Classical and Bayesian Instrument Development software program. Correlation analysis between FTND and AUTOS subscale scores was performed along with multiple linear regression analyses to identify the predictors for AUTOS subscale scores. **Results:** The symptom type-wise subscales of AUTOS and the overall scale demonstrated good internal consistency reliability (Cronbach alpha ≥ 0.758). Significant positive correlation was observed between age, years of smoking, FTND score, and all the AUTOS subscale scores. Linear regression analyses showed that the number of years for which the subject had been smoking was a significant predictor of all the three AUTOS subscale scores. **Conclusion:** AUTOS was observed to be a very useful tool with good internal consistency reliability that measures tobacco dependence in consistency with FTND among South Indian population, and while doing so, it captures the various forms of tobacco dependence in an independent manner.

Keywords: Confirmatory factor analysis, tobacco dependence, withdrawal symptoms

Introduction

The ever-increasing tobacco use is one of the significant problems world is facing today. The habit of tobacco consumption is responsible for over 8 million deaths across the globe.^[1] The years of life lost due to tobacco use have been on a consistent rise worldwide, with developing countries contributing around 70% to these premature deaths.^[2] In India, it is reported by a study from the World Health Organization that 1% of the nation's GDP is lost to the disease burden posed by tobacco consumption and the associated mortality.^[3] It has been estimated that the revenue obtained from tobacco accounts for only 12% of the costs associated with tobacco use, implying that the nation's

economy loses Rs 8.16 for every rupee of tax obtained from tobacco products.^[3]

It is noteworthy that in spite of the huge efforts being directed toward reducing the use of tobacco products in India in the form of awareness campaigns and increased taxation on tobacco products, etc., the achievement of desired outcomes remains a distant dream with nearly 29% of the adult Indian population using tobacco in some form according to the Global Adult Tobacco Survey, India (2016–2017).^[4] The Government of India in association with the Dental Council of India has taken an initiative and made it mandatory to establish tobacco cessation clinics in teaching dental institutions across the country.^[5] Similar efforts have been

underway with regard to full integration of tobacco cessation counseling in undergraduate medical curriculum.^[6] Though the attitudes of students and faculty at teaching health-care institutions with regard to provision of tobacco cessation counseling at these settings are equivocal, international experiences suggest positive influence of tobacco cessation counseling on bringing down the use of tobacco among subjects seeking care at these facilities.^[7-10] Nevertheless, it has been a common observation that health-care providers belonging to diverse disciplines who take part in tobacco cessation counseling must be equipped with the knowledge on multitude of reasons for nicotine dependence and in various pharmacologic means of tobacco cessation counseling besides the motivational persuasion of potential quitters.^[11]

It is to be discerned that nicotine dependence is a complex disorder. People with nicotine addiction consume tobacco products at differing doses and frequencies depending on the demands of the body.^[12] Nicotine traverses through the blood-brain barrier and quickly gets distributed into the cerebral tissue. Tobacco users experience a sense of arousal, relief from stress, and improvement in concentration after the intake of the tobacco products.^[13] However, cessation of tobacco use among these subjects result in manifestation of withdrawal symptoms such as irritability, anxiety, depression, etc., which need attention from health-care professionals. Understanding the nicotine dependence of an individual is therefore quintessential in the course of provision of tobacco cessation counseling as it also determines the likelihood of quitting the habit of tobacco consumption. Autonomy over smoking scale (AUTOS) is a 12-item psychometric tool developed and previously validated among other populations outside India.^[14-16] With this background, the objective of this study was to assess the psychometric properties of AUTOS among subjects seeking care at a teaching dental institution in the South Indian state of Andhra Pradesh.

Materials and Methods

This study was conducted among patients seeking oral health care at a teaching dental institution in the South Indian state of Andhra Pradesh. The study was conducted between January and December 2017. AUTOS is a 12-item psychometric tool, to assess the autonomy over smoking, originally developed and validated at the University of Massachusetts Medical School.^[14] The scale consisted of items relating to three symptom types as follows: withdrawal symptoms, psychological dependence, and cue-induced craving. All the items were administered on a 4-point Likert scale ranging from “not at all” to “very well.” Thus, the symptom type-wise scores in AUTOS range from 4 to 16, whereas the overall scale score ranges from 12 to 48. The scale demonstrated excellent internal consistency reliability in previous studies (Cronbach alpha ≤ 0.91) and showed concurrent validity with the Fagerstrom test for cigarette dependence.^[15] The 12-item

scale was translated to the local language Telugu by a bilingual expert, which was then back-translated to English by another person proficient in both the languages. Minor modifications in the local language version were made to achieve semantic equivalence. A trained interviewer administered the scale to the participants in a quiet room. Details pertaining to participants’ age, gender, and years of smoking were collected. Fagerstrom test for nicotine dependence (FTND) was also administered along with AUTOS. The average time taken for the conduct of each interview was 8 minutes. All the participants signed a written informed consent before the administration of the scales. Ethical approval for this study [SJDC/CEC/2015-2016] was obtained from the Institutional Ethical Committee of St Joseph Dental College, Eluru, on December 22, 2015. A total of 199 subjects satisfying the eligibility criteria of self-reported current smoking who were willing to participate in the study constituted the final sample. This study aimed to verify the factor structure of AUTOS by performing confirmatory factor analysis (CFA). CFA was performed using Classical and Bayesian Instrument Development software program.^[17] The sample size of 199 considered in this study was in accordance with the sample size requirements for structural equation models suggested by Wolf *et al.*^[18] IBM SPSS version 20 software was used to check the internal consistency reliability of the AUTOS subscales. Further, correlation analyses between AUTOS subscale scores, age, years of smoking, and FTND scores were evaluated using Spearman correlation coefficient. Linear regression was performed to check the amount of variance in each of the symptom-wise subscale scores and the overall scale score that could be explained by age of the participant and the number of years for which the participant has been smoking.

Results

The mean age of the study participants was 43.92 ± 16.48 years and the mean duration for which the participants have been smokers was 19.16 ± 14.77 years. All the study subjects were males. The symptom type-wise subscales of AUTOS demonstrated good internal consistency reliability (Cronbach alpha ≥ 0.758). Table 1 presents the corrected item total correlations, Cronbach alpha values for the AUTOS subscales along with Cronbach alpha values with deletion of individual items. Both the unidimensional factor structure and the symptom type-wise tridimensional factor structure of AUTOS were verified in CFA. Table 2 presents the factor loadings of items in both the unidimensional and tridimensional models obtained using CFA. Table 3 summarizes the model fit indices of both the CFA models evaluated. It was observed that the symptom type-wise tridimensional model showed good model fit indices compared to the unidimensional model. Significant positive correlation was observed between age, years of smoking, FTND score, and all the symptom type-wise

Table 1: Internal consistency reliability statistics and the corrected item total correlations of the symptom type wise subscales of autonomy over smoking scale

Measure	Item	Corrected item total correlation	Cronbach alpha if item deleted	Cronbach alpha
Withdrawal symptoms subscale	When I go too long without a cigarette, I get impatient. (Item 1)	0.661	0.814	0.846
	When I go too long without a cigarette, I get strong urges that are hard to get rid of. (Item 2)	0.764	0.768	
	When I go too long without a cigarette, I lose my temper more easily. (Item 3)	0.588	0.845	
	When I go too long without a cigarette, I get nervous or anxious. (Item 4)	0.724	0.787	
Psychologic dependence subscale	I rely on smoking to focus my attention. (Item 5)	0.667	0.732	0.805
	I rely on smoking to keep from feeling bored. (Item 6)	0.618	0.756	
	I rely on smoking to deal with stress. (Item 7)	0.618	0.758	
	I would go crazy if I couldn't smoke. (Item 8)	0.581	0.774	
Cue-induced craving subscale	When I feel stressed, I want a cigarette. (Item 9)	0.466	0.746	0.758
	When I see other people smoking, I want a cigarette. (Item 10)	0.605	0.672	
	When I smell cigarette smoke, I want a cigarette. (Item 11)	0.538	0.711	
	After eating, I want a cigarette. (Item 12)	0.621	0.663

AUTOS, autonomy over smoking scale.

subscale scores of AUTOS [Table 4]. Linear regression analyses showed that the number of years for which the subject had been smoking was a significant predictor of all the three AUTOS subscale scores [Table 5].

Discussion

This study tested the dimensionality of AUTOS among subjects seeking oral health care at a teaching dental institution in southern India by the conduct of confirmatory factor analysis. The study results support the symptom type-wise factor structure of AUTOS unlike the unidimensional factor structure observed in previous studies.^[14,19] It is important at this juncture to underscore the fact that AUTOS was originally developed with a notion that the manifestation of tobacco dependence can be manifold and three domains of withdrawal, psychologic dependence, and cue-induced craving were identified as different forms of tobacco dependence.^[14] Such explicit distinction of items in

the scale to be belonging to different domains holds an assumption that the factors responsible for each of these forms of tobacco dependence, the underlying mechanism of development of dependence, and the influence of each of these forms of dependence on the ability of the subject to quit tobacco are different.^[19] Thus AUTOS possess an intrinsic tridimensional factor structure which was also established among the validation studies performed among adolescent smokers. Nevertheless, confirmatory factor analysis demonstrated a unidimensional factor structure of AUTOS among adult smokers of the United States America, the reason for which was identified to be the diminishing boundaries between the AUTOS subscales with increasing age.^[19] However, in the present study performed among a

Table 3: Comparison of model fit indices of both the unidimensional and tridimensional models tested in CFA

Model fit index	Unidimensional model	Tridimensional model
Model fit test statistic (df, P-value)	261.87 (54, 0.0001)	98.45 (51, 0.0001)
RMSEA (90% CI)	0.14 (0.12–0.15)	0.069 (0.048–0.089)
Tucker–Lewis index	0.953	0.989
Comparative fit index	0.961	0.991
SRMR	0.1	0.062
WRMR	1.602	0.982

* Statistically significant.

sample of South Indian adult population, the mean age of whom was 43.92 ± 16.48 years, the tridimensional factor structure of AUTOS showed better model fit indices compared to the unidimensional factor structure. Each of the three subscales of AUTOS demonstrated good internal consistency reliability (Cronbach alpha ≥ 0.758). Similar observations were reported by Wellman *et al.*^[16] The reasons cited for diminishing boundaries between AUTOS subscales with increasing age were the evolution of physical dependence early in the process of habituating tobacco consumption and the increasing association between physical dependence and psychologic dependence, cue-induced cravings with increasing durations of smoking.^[20,21] Though higher AUTOS subscale scores were observed in this study with increasing age, the explanations surrounding the fading distinction between subscales with age did not hold well among the population considered in the present study. Prospective studies that follow subjects from adolescence to late into their adulthoods may be necessary to acquire concrete insights into the differential inter item relations of AUTOS for participants from different age groups. It was observed in this study that the subscales of psychologic dependence and cue-induced cravings were the most correlated of the three subscales. All the three subscales of AUTOS showed good concurrent validity with the FTND score. Of the three subscales, withdrawal symptoms demonstrated strongest positive correlation with FTND score which could be understood in light of the nature of FTND items that attempt to document the compelling feelings of smokers to smoke. These findings were consistent with the results reported by DiFranza *et al.*^[22] The AUTOS subscale scores showed weak to moderate positive correlations with the years for which the subjects have been smoking. Contrary to these findings, strong positive correlation between AUTOS scores and duration, frequency of smoking were found in the studies conducted among the US and German populations.^[14,15] One of the limitations of this study is its reliance on a convenience sample of subjects seeking care at an oral health-care facility which limits the ability of the investigators to define the population from which the sample was drawn. Another potential limitation in this study is the social desirability bias inherent in all self-reported data, particularly with regard to a deleterious habit which is known to be harmful both for the individual and the society in a broader context.

Conclusion

Within the limitations of this study, AUTOS was observed to be a very useful tool that measures tobacco dependence in consistence with FTND among South Indian population, and while doing so, it captures the various forms of tobacco dependence in an independent manner. Future directions for research include the conduct of longitudinal studies that document the transformations in the factor structures of

AUTOS with time and the reasons for such dynamic nature of association between items belonging to different symptom domains.

Peritraumatic distress in Southern Indian inhabitants during second wave COVID-19 pandemic: A community-level survey

Srinivas Ravoori¹, Parveen Sultana Shaik¹, Suresh C. Yaddanapalli¹, Nijampatnam P. M. Pavani¹, Nadeem Ahmed Khan², Varsha Yeramala²

Department of ¹Public Health Dentistry and ²Undergraduate Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

ABSTRACT

Introduction: As coronavirus disease 2019 (COVID-19) is a new disease which has ruining and dismantling the harmony of people internationally, its development and spread, creates turmoil, nervousness and dread among worldwide. **Aim:** To evaluate seriousness of peritraumatic problems among southern Indian inhabitants during the COVID-19 pandemic. **Methodology:** A referral sampling technique was continued until a sufficient sample size was reached, while this self-administered survey catches insights about depression, fears, psychological change, evasion cognitive change, and collectively quantifies the stress on a scale of 0–60. Expressive factual examinations were utilized to sum up clear cut information and inferential measurable investigations included Chi-square tests and Pearson's correlations were done. **Results:** The study included only those participants who understood English and had access to the internet. Inconsequential outcomes were found among gender in which both male and female members frequently showed apprehension and nervousness about COVID-19. 44.8% tried not to watch the news on COVID-19 as they were excessively frightened and make frenzy to family members. 90.9% of participants with lower education levels were more stressed over the thought of getting COVID-19 when showing manifestations related with the novel corona virus, which was statistically significant. **Conclusion:** The current assessment shows that almost all the study participants have felt restless, uncomfortable and terrified of watching the news whilst stressed over appearances related with COVID-19 due to their greater access to information.

Keywords: Coronavirus, mental stress, pandemic, peritraumatic distress

Introduction

Since the outbreak of affirmed case arose in Wuhan, China, in December 2019, the novel coronavirus disease 2019 (COVID-19) has spread around practically the entirety of the world at an alarmingly quick rate influencing more than 7 million individuals and causing more than four lakh's deaths.^[1,2]

The Government of India forced a cross-country lockdown beginning from March 24, 2020, results in complete limitation of movement outside the house except for basic supplies or other crisis reasons, which has unhinged the lives of people across the country.^[3]

As COVID-19 is a new disease and are having the most devastating effects globally, its emergence and spread causes confusion, anxiety, and fear among the general public.^[4,5] Nations have been burdened with COVID-19 for more than one year and presently going through the another possibility of third flood of COVID-19. Starting on February 3, 2021, there have been

How to cite this article: Ravoori S, Shaik PS, Yaddanapalli SC, Pavani NP, Khan NA, Yeramala V. Peritraumatic distress in Southern Indian inhabitants during second wave COVID-19 pandemic: A community-level survey. J Family Med Prim Care 2022;11:4730-5.

more than 100 million affirmed cases throughout the planet.^[2] A second wave beginning in March 2021 was much devastating than the first, with shortages of vaccines, hospital beds, oxygen cylinders, and other medicines in parts of the country. On April 30, 2021, it became the first country to report over 400,000 new cases in 24 hrs.^[6]

Outbreaks such as the COVID-19 pandemic have a negative psychological impact which increases demand for mental health care needs. Factors like lockdown, social isolation, disruptions in life routines may cause peritraumatic distress.^[7] During the outbreak of these infections, several psychiatric co-morbidities such as depression, panic attack, anxiety, psychomotor excitement, suicide, and stress symptoms were reported.^[8]

The most noteworthy quantities of new deaths were accounted for from India (7875 new deaths; 0.6 new deaths per 100,000; a 69% increment), Indonesia (885 new deaths; 0.3 new deaths per 100,000; a 26% lessening), and Bangladesh (622 new deaths; 0.4 new deaths per 100,000; a 39% increment). Because of the increasing COVID cases in India, during the second wave pandemic, the fundamental motivation behind the current examination is to quantify mental experiencing like pressure, nervousness, and dread among the overall population.^[9] A second wave of coronavirus swept across the country causing widespread destruction and death. While we're still unclear, there are countless reports of a third wave of COVID arriving, which could be just as intense and put a strain on healthcare resources.^[10] Despite the fact that anxiety and depression are the most common mental health problems encountered in primary care. The difficulty in recognizing and diagnosing mental health problems is a multifaceted problem influenced by the knowledge and attitudes of primary care physicians. Diagnosing and treating a mental health problem in primary care begins with the clinician's response to a patient disclosure of emotional problems. So, it is important for primary care physicians to perceive, evaluate, and react to this distressing pandemic situation.^[11]

Health crises such as the COVID-19 pandemic lead to psychological changes, not only in the medical workers but also in the citizens, and such psychological changes are initiated by fear, anxiety, depression, or insecurity.^[12] Thus, this study aimed to assess the severity of peritraumatic distress among the general population during the COVID-19 pandemic.

Methodology

A cross-sectional investigation was conducted among general population of Andhra Pradesh, India in April 2021. With a certainty level of 95%, the assessed test size was 967 utilizing an edge mistake of 5%. A cold-calling sampling method was adopted in the study, and the questionnaire was sent to the contacts of the surveyors. All the participants were further requested to forward the tool in their respective contacts. Data were gathered utilizing Google forms in English language comprising demographic details like age, gender, education,

work, and recently approved peri-traumatic distress scale which was adjusted by the current investigation region, and the link was shared among various platforms. Participants were requested to forward the questionnaire further to their contacts. Obscurity was guaranteed as there is no close-to-home contact, as only the responses were recorded in the study. This self-administered survey catches insights about depression, fears, psychological change, evasion cognitive change, and collectively quantifies the stress on a scale of 0–60. A modified peri-traumatic index scale score under 20 shows '**low or no stress**', 21–40 demonstrates '**gentle to moderate stress**' and more than 41 shows '**extreme stress**'. Study approval was taken from the institutional review board (36/IRB/SIBAR/2021). Before the start of the study, an informed consent was obtained from all the individuals willing to participate and ensured their participation was voluntary and anonymous. The investigators assured the participants that the data shall be kept confidential and shall only be used for research purposes. The information was pooled, arranged, and examined utilizing SPSS version 23 (IBM Corp., Armonk, NY, USA). Descriptive statistical analyses were used to summarize categorical data and Inferential statistical analyses included Chi-square tests and Pearson's correlation were done. Straight relapse examination was finished utilizing stepwise factor determination to decide critical indicators of mental misery while P value ≤ 0.05 was considered as statistically significant.

Results

All the participants were above 18 years of age and of Indian origin, while study included only those participants who understood English and had access to the internet. The majority of respondents had a degree and above qualification, 901 (93.2%), and 912 (94.3%) were employed. There were 967 participants from both genders (636 males, 65.8%, and 331 females, 34.2%). In the present study, 1.3% are health care workers and the remaining 98.7% are general public [Table 1].

About 46.4% of study subjects felt more nervous and anxious while only 9.7% of the participants were normal, irrespective of situation. The majority of the participants felt sympathetic toward COVID-19 patients and their families. Almost all the age groups are worried and felt nervous and scared of watching the news about COVID-19. At the same time majority of the participants worried about symptoms associated with COVID-19. 38.2% of the participants said that they don't believe fake news without confirmation and would not like to share it with others. 44.8% sometimes avoid watching the news on COVID-19 as they were too scared as it could make to family members panic. Similarly, 65.7% of respondents felt helpless, and angry about people around them, while 34.9% were occasionally irritable and have frequent conflicts with family members than in normal times [Table 2].

Participants with lower education level are more scared to watch the news, which was statistically significant ($P \leq 0.01$). 90.9% of

participants with lower education levels were more worried about getting infected when showing symptoms associated with the novel coronavirus, which was statistically significant [Table 3].

The majority of the study subjects in all the participated age groups showed worried about symptoms associated with COVID-19 which showed no significant results. But older age respondents showed more often back pain/chest distress, which was statistically significant ($P \leq 0.042$). [Table 4].

Insignificant results were found among gender in which the majority of both male and female participants often showed nervousness and anxiety about COVID-19. Statistical difference was found between male and female participants about back pain

and chest distress, which was more often in male participants than female subjects [Table 5].

Discussion

The majority of respondents in the present study had an education level of degree and above, while most of them were employed. The reason may be because of online study, most of the educated people might have shown interest to participate. This is similar to the study by Hyejung Yoon *et al.*^[2] and Harshal Sri Ram Sathe *et al.*^[3] Of the total sample, more than half the study subjects were males, which was in contrast to the study done by Vikram Ramasubramanian *et al.*^[13] and similar to the study by Harshal Sri Ram Sathe *et al.*^[3]

In the present study, most of the respondents were from 25–34 years of age group and study subjects of 35 years and above were scared to watch the news regarding novel coronavirus when compared to younger age groups this may be due to the fact that responsibilities in family and work tensions makes them scared to watch COVID-19-related news. But studies done by Naina Wakode *et al.*^[14], Sikandar A. Qalati *et al.*^[15], and Vikram Ramasubramanian *et al.*^[13] were in contrast to the present study, while similar results were reported by Mostafa A. Abolfotouh *et al.*^[16]

The major part of the participants felt sympathetic towards COVID-19 patients and their families, because of unexpected situations which effected families, financial strain and the lack of support will effect psychological conditions, so it is important for the primary care physicians to practice empathy during pandemic situations, which was on agreement with the study done by Dhar Bahadur Shrestha *et al.*^[17] and the results were contradictory to the study done by Vikram Ramasubramanian *et al.*^[13]

When asked about irritable and frequent conflicts with their family, 36.9% said that they never had any conflicts and 34.9% had occasionally. The coronavirus has led to sweeping changes and disrupting in nearly every aspect of daily life, loss of job, financial matters might be a source of stress contributing to

mental health problems. This was in accordance with the study done by Yan Guo *et al.*^[18] and different from the study done by Vikram Ramasubramanian *et al.*^[13]

Only meager of the study populations are health care workers while majority was general public. Though nearly half of

them often felt nervous and anxious toward COVID-19, and majority of the participants are worried most of the time about getting infected when showing symptoms associated with the novel coronavirus. The difference was seen among educational qualifications, where participants with lower education levels showed more worried about getting infected when showing

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

symptoms associated with novel coronavirus than higher education levels, this may be the reason that higher level of education might practice better coping strategies, which was relevant to a study done by Mogesie Necho *et al.*^[19] Naina Wakode *et al.*^[14] and which was in contrast to the study by Dhar Bahadur Shrestha *et al.*^[17] and Jianyin Qiu *et al.*^[1]

In the present study, 35.6% occasionally concentrated on exercises/yoga than before, maybe due to the reason that being physically and mentally fit can fight against stress which is necessary for everyone and majority of the respondents also changed their dietary habits, this might be due to awareness given by government and health care workers to improve immunity against COVID-19, which was in contrast to a study done by Dhar Bahadur Shrestha *et al.*^[17]

More than half of the respondents reported that they could not stop themselves from collecting information about coronavirus and share information with others, as access to information is greater through media, “We’re not just fighting an epidemic; we’re fighting an infodemic”, as said by WHO Director-General Tedros Adhanom Ghebreyesus. While the results were in contrast to a study done by Priscilla Samson *et al.*^[7]

The majority of the participants often showed nervousness and anxiety about COVID-19. But when asked about back pain and chest distress, which was seen more often in male participants than female subjects, which was different from the study done by Mark Shevlin *et al.*^[20] which could be because of the fact that males being a head of the family, they experience more pressure and stress with financial and family responsibilities which might increase in this perplexing COVID situations. Overall, 86.7% of participants had mild to moderate levels of stress which was, in contrast to a study done by Vikram Ramasubramanian *et al.*^[13] and a total of 65.7% of participants felt helpless, angry about people around, government, and media which was similar to the study by Priscilla Samson *et al.*^[7] Plethora of psychosocial issues, such as contamination fears, dissatisfaction, fatigue, lockdown sway, a flood of deception (infodemic), bits of hearsay, different paranoid ideas, lacking supplies, monetary misfortune, and social stigma about the disease have negatively affected psychological well-being all around the world during this pandemic.

Results of the present study depict that the stress was higher among the study participants as the second wave was characterized by high morbidity rates, oxygen supply shortage, availability of meager beds in hospitals, finally with the emergence of mental health problems.

Mental health is an essential component of overall health. In India, counseling about mental health issues is still viewed as a social stigma, which is why people avoid seeking treatment for mental illness. The mental health of people prone to depression

and anxiety disorders should not be overlooked and efforts to varying degrees should be made to identify and maintain morale. In the era of COVID-19, panic disorder is very common among the public and there is a need to regulate schools, offices and homes to provide counseling services to all age groups so that all Indians can benefit healthy mental health and well-being.

Key points

- Participants with lower education level are more scared to watch the news, and were more worried about getting infected when showing symptoms associated with novel corona virus.
- Regardless of age, almost all the participants worried about symptoms associated with COVID-19, while back pain and chest distress was more common in males than females.

Conclusion

The COVID-19 emergency and the going with lockdown have without a doubt influenced each person in for sure and mental sufferings in human existence everywhere. The current investigation shows that practically almost all the study population are stressed and felt apprehensive and frightened of watching the news and stressed over manifestations related with COVID-19. It would likewise be valuable to analyze the content that individuals are getting from social networks and assist them with fostering the important abilities to have the option to channel such information. Likewise, the public authority should share however much data as could reasonably be expected with the general population, such as knowledge about COVID-19, every day flare-up status, and the public authority’s pandemic counteraction technique; this might assist with reducing psychological stress. Multisectoral comprehensive strategies and resilient system are required to tackle the direct and indirect effects of pandemic.

Limitations

- This study has some limitations. First, there are always limitations in the use of self-report questionnaires.
- Questionnaires are not diagnostic tools. The choice of the cut-off point is arbitrary and depends on the subjective of the participants.
- On the one hand, anonymity has allowed people to express themselves more freely; on the other, we have no data on the truthfulness of the information.
- The study cannot be generalized as it is an online survey, only educated and those who has access to the devices and internet has answered the questionnaire.

Discernment in Practicing Nonpharmacological Modes of Intervention in Combating SARS COVID-19: Reflections of Dental Patients in India

Suresh Chand Yaddanapalli, Parveen Sultana Shaik, Srinivas Pachava, Srinivas Ravoori, Raja Sekhar Potluri

Department of Public Health Dentistry, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Background: As a massively polarizing practice, concealing or face covering has emerged in the midst of the coronavirus disease 2019 (COVID-19) pandemic. Given the increasing speculation regarding therapeutic control measures, nonpharmacological approaches offer promising successful mitigation in the battle against severe acute respiratory syndrome (SARS) COVID-19. The evaluation of public capacity, prospects, and actions offers recommendations for public oversight of the implementation of prevention activities. Hence, this investigation was aimed to explore the discernment in practicing nonpharmacological modes of intervention in combating SARS COVID-19 among a group of people, dental patients. **Materials and Methods:** A pictorial questionnaire survey was done using convenience sampling, aimed at participants visiting the triage facility of the institution to capture their discernment in practicing nonpharmacological modes of intervention for 3 months. **Results:** A total of 6015 individuals with a mean age of 35.44 ± 14.20 years participated in the study. The majority of the participants were in the age group of 18–30 years ($n = 2340$, 38.9%) with female ($n = 3105$, 51.6%) and urban ($n = 3745$, 62.3%) predominance. Most of the study participants had purchased cloth masks ($n = 2980$, 49.5%) and had spent about 10–50 INR per mask ($n = 4050$, 80.6%). Patients have reported that the usage of a mask ($n = 1330$, 22.1%) was the most difficult measure to follow and also stated that sanitizing hands ($n = 2505$, 41.6%) was the easiest measure to follow during this pandemic. Crowding in the market ($n = 2255$, 37.5%) and placing masks around the neck ($n = 735$, 12.2%) were infringements served in their surroundings. Irrespective of educational qualification touching the outer area of the mask was the most common noncompliance reported by the participants which were statistically significant ($P = 0.0001$). **Conclusion:** The study participants have divulged that usage of masks and following social distance in public transport were the most difficult preventive measures of SARS COVID-19 to follow. Evaluating the attitudes of public in preventive procedures for COVID-19 can pave the way to make comprehensive guidelines.

Keywords: COVID-19, dental school, noncompliance, nonpharmacological interventions, pandemic, patient

INTRODUCTION

Having affected more than 72,196,732 confirmed cases and 1,630,521 deaths worldwide, the severe acute respiratory syndrome (SARS) coronavirus disease 2019 (COVID-19) pandemic continues to evolve at a rapid pace.^[1] The vulnerability index for the management of and response to the SARS COVID-19 epidemic in India shows that Andhra Pradesh score as 0.714, where 1.0 is the most vulnerable and 0.0 least vulnerable.^[2] The spread of the new COVID has influenced individuals everywhere in the world, state and Local governments are making clearing moves

to stop the spread of the illness and alleviate the general well-being and financial effect of the flare-up.^[3] Analysts and legislative authorities consider this pandemic as challenging with huge legal and procedural concerns including basic security, legitimate perspective, opportunities, and financial impact as communities, states, and countries respond to the scourge.^[4]

Concealing or face-covering among the SARS COVID-19 pandemic has arisen as a profoundly polarizing practice. With given uncertainty mounting on therapeutic measures in controlling, nonpharmacological methods offer promising effective mitigation in combating SARS COVID-19.^[5] Assessing public capability, opportunity, and behavior provide a guide to monitor the public in adopting preventive practices. One such method of assessing is through questionnaire surveys. Validated and short questionnaire surveys that are aimed at capturing behavior can offer an insight into issues concentrated in adopting preventive behavior.^[6]

Fearing transmission of disease in the dental practice majority of the dentists are yet to resume full-fledged practice.^[7] Among these circumstances and in the wake of public interest, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, opened its complete oral health services in August 2020, whereas in earlier months of lockdown it provided emergency services. To minimize the need for personal protective equipment, a Kiosk center with glass supported by indoor and outdoor audio for Triage purposes has been erected under Public Health Dentistry Department in the portico of the college to screen patients through health interviews to rule out SARS COVID-19 before they are sent to the Oral Medicine and Radiology Department for oral examination. Hence, with this background, a study was done to explore practices of nonpharmacological modes of intervention in combating SARS COVID-19 by dental patients visiting institution.

MATERIALS AND METHODS

Owing to the fact that pictures are better at communication than written words, as one picture is worth a thousand words, pictographs were used as a medium to discern preventive measures in practicing nonpharmacological modes of intervention in combating SARS COVID-19. This was a cross-sectional pictorial questionnaire survey done on convenience sampling, which was aimed at participants visiting dental institutions to discernment in practicing nonpharmacological modes of intervention. The participants are reflective of the general population of this area in terms of their nativity and belongingness to all walks of life. This study was done over 3 months (September 2020 to November 2020) on 6015 individuals who were chosen on a random basis among 300 patients on an average visiting per day for oral health needs, interviews were made at the triage section of the institute asking for their perception's and practices regarding the various preventive measures after obtaining consent.

The questionnaire consisted of demographic data and items related to preventive measures followed and noncompliance observed concerning SARS COVID-19. Two panels were utilized for this purpose. The first one with color pictographs attached on SARS COVID-19 preventive measures, and on the other panel, the pictures of noncompliance were placed. The panels consisting of pictographs of preventive measures followed and noncompliance practices observed in the family

and surroundings were finalized from the pilot study done among 54 participants with good reliability (Cronbach's alpha [α] = 0.82).

Ethical approval

A detailed review of the multifaceted aspect of the research and about the consent of the participants was elaborated for approval from the Institutional Ethical Committee (Pr. 255/IEC/SIDS/2020), while the anonymity of the study participants was secured by following the ethical principles of the World Medical Association Declaration of Helsinki.

RESULTS

A total of 6015 individuals with a mean age group of 35.44 ± 14.20 years participated in the study. The majority of the participants belonged to 18–30 years' age group ($n = 2340$, 38.9%) with female ($n = 3105$, 51.6%), urban ($n = 3745$, 62.3%), and marital status ($n = 4025$, 66.9%) predominance. It was found that 49.5% of the individuals in the study were illiterates ($n = 2975$) followed by participants with high school education ($n = 805$, 13.4%) while with reference to occupation majority of them fell under semi-profession category ($n = 1845$, 30.7%) [Table 1].

Most of the study participants used purchased cloth mask ($n = 2980$, 49.5%) followed by custom made/free cloth mask ($n = 2220$, 36.9%) [Figure 1]. Regarding the amount spent on purchasing each mask, the leading percentage of the individuals spent about 10–50 INR (Indian rupees) ($n = 4050$, 80.6%) [Figure 2]. Many individuals reported that maintaining social distance in the public transport ($n = 1530$, 25.4%) and the usage of the mask ($n = 1330$, 22.1%) were the most difficult practices to follow during this pandemic. They also perceived that sanitizing hands ($n = 2505$, 41.6%) and using hand wash ($n = 1835$, 30.5%) were the easiest practices to follow [Table 2].

Many participants observed that crowding in the market ($n = 1300$, 21.6%) and touching the outer area of the mask ($n = 940$, 15.6%) were the derelict of the COVID-19 measures by their family members, while it was warranted that crowding in the market ($n = 2255$, 37.5%) and placing mask around the neck ($n = 735$, 12.2%) were infringements observed in their surroundings [Table 3]. When comparing the noncompliance practices of the participants with their educational level, almost all the participants with various education levels have acquiesced that touching the outer area of the mask as the most disregard practice followed by them, except for the participants with primary school level education, where $P = 0.001$ which was statistically significant [Table 4].

DISCUSSION

This study was done to explore the reflections of the society through dental patients visiting a dental organization in rehearsing nonpharmacological methods of mediation in battling SARS COVID-19. Surveying participants who are

going to dental offices on identifying with receiving preventive conduct in battling COVID-19 can help in better treatment conventions and furthermore provide some insight into the

unsafe conduct of the subject, encouraging dental specialists in better managing through appropriate guidelines and alterations.^[8] The desire for the prevention by an individual relies on the psychological need maintain which is influenced by means of autonomic and controlled motivation which accordingly depends on their attitude, subjective guidelines, and perceived behavioral control. Segregation toward the estrangement of and the making of people who wear a face mask in public areas or social gatherings that empower the obliviousness of social separation measures may sabotage a person’s relatedness and emotional standards with regard to COVID-19 avoidance.^[9] The absence of network selection to preventive measures for shortening coronavirus is because of fluctuated reasons which incorporate regulatory omissions, being critical, dread and nervousness, counterfeit news, accepted practices, culture, and governmental issues.^[10,11]

One of the reasons for failure in preparedness for epidemics is the lack of a comprehensive National Public Health Act in India. The number of enactments gives gigantic capacity to general well-being functionaries that should be figured out. General health authorities, such as examiners and well-being officials working with different assignments not only have a few essential requirement paraphernalia but are also influenced by defilement, similarity, giving grants, licenses, and enlistments; giving regulatory requests; forcing common punishments, and directives. Conclusively, there are one or different purposes behind not executing these well-being enactments in a genuine sense and general well-being stays defenseless against social, mental, and actual danger factors.^[12-14] Three principal factors hold up traffic of counteraction; individuals do not appreciate the dangers they run, it conflicts with human instinct for individuals to quiet themselves down in inflexible disengagement as a method for securing others, what’s more, individuals regularly unwittingly go about as a proceeding with risk to themselves as well as other people.^[15]

We are at a point in the development of living through a pandemic where the individuals who have returned in the operatory are getting more acclimated with giving patient consideration inside the bounds of what is called “the new

Chi-square test, $P < 0.001$ (Highly statistically significant). 1 - Social distancing without mask, 2 - Informal way of covering face with mask, 3 - Hanging mask to nearby objects, 4 - Frequently adjusting mask, 5 - Touching outer area of the mask, 6 - Nose/eye touching while wearing mask, 7 - Crowding in markets, 8 - Crowding near delivery/cash counters, 9 - Chinstrap, 10 - The ear hanger, 11 - Neck warmer, and 12 - Wadded mask in their pocket

normal.” Depending on convictions, comfort level, and neighborhood guidelines, a portion of our patients is returning with a “the same old thing” mentality. Others are careful, however agreeable, and afterward, there are the individuals who are not prepared to return by any stretch of the imagination. The examination applies an unmistakable investigation to dental patients’ information in the extraordinary period and presents notable and important findings of dental visits relating to socioeconomics. There is a clear contrast between the

general numbers of people even in these emergency times in looking for dental administrations which mirrored that females use more dental administrations than men inferable from different reasons. In the current observation, the proportion was 51.6% females to 48.4% males.^[16]

Purchased/custom made/free cloth masks were the personal choices of the study participants as a nonpharmacological means of a preventive measure adopted as they are affordable, available, accessible, reusable, and recyclable due to

which they are widely used as a public health intervention strategy.^[17]

In this study, it was observed that crowding in the market, touching the outer area of the face mask, and usage of the mask as a neck warmer were the infringements observed by the participants in their family and surroundings. Isolation and social distancing measures, including edicts to stay at home, have been brought into place globally to reduce the transmission of the virus, but at a huge cost to individuals and society. In addition to these measures, other effective interventions to increase adherence to behaviors that individuals in communities can enact to protect themselves and others: as reported by Glynda Alves that 90% of Indians are aware of wearing a mask as a preventive measure, but only 44% were wearing a mask where discomfort was revealed as a key reason for noncompliance.^[18] This study provides the evidence to start applying behavioral science methods and models to understand and modify the individual's perceptions and nonpharmacological practices.^[19]

The amount spent on each mask by the individuals was about 10–50 INR which might be due to the reason that the amount India spends on public health per capita every year is 1112 INR less than the cost of a single consultation in the country's top private hospitals or roughly the cost of a pizza at many hotels, that comes to INR 93 per month or INR 3 per day.^[20] The average cost of manufacturing these surgical face masks was around 40–45 paisa, while that for N95 mask is about ₹10–12, but due to market dynamics, these were being sold at a much higher price which was not affordable.^[21]

For the vast majority of people, wearing a mask is a new thing. While we as a whole conform to wearing masks out in the open, it is significant we attempt to expect as meager as conceivable about others, dependent on whether they are wearing one. It is anything but difficult to make a hasty judgment. As wearing a mask in broad daylight turns out to be more normal in numerous parts of the world, either on the grounds that it's obligatory where you live or on the grounds that you decide to wear one, it very well may be enticing to expect individuals who do not wear masks are reckless, misinformed, or egotistical. Dental specialists and individual dental patients are no exemption from this philosophy as the authors perceived. Understanding public capacity, opportunity, and motivation in receiving preventive strategy are the critical hotspots for conduct change; if not, any endeavor to change the conduct will just turn into purposeful publicity rather an adjustment in conduct.

Individual social desirability bias cannot be excluded owing to the fact that questionnaire studies elicit a conscious positive response; however, when asked about the most common preventive measure in combating SARS COVID-19 was not followed in the surroundings, and the family was found to be crowding in markets which reflected the lapse in following preventive measure as a whole in the community.

CONCLUSION

One of the most basic needs for a dental patient is the availability of transport in availing oral health care, with the pandemic majority of the participants reported that following social distancing in the public transport is the most difficult preventive measure reflecting the need to address the issue. While crowding in markets is the most common noncompliance observed within the family and in surroundings highlighting the importance of the need for strict implementation of legislative measures.

Overall, mask etiquette was the most difficult to follow hence required upliftment of cognitive skills on the usage of masks among the community. Noticing a patient's preventive conduct is one of the vital accomplishments for productive dental administrations conveyance among the corona infection pandemic. Dental foundations may end up being upheavals of cases if patients who go into the grounds are not checked or perceived. Effective guidance and making to comprehend guidelines are conceivable just on investigating patient's mentalities toward adopting preventive protocols for SARS COVID-19.

Abstract

Introduction: Different rates of dental caries prevalence are experienced among different populations due to the influence of various demographic, political, and socioeconomic factors. **Aim:** To assess the prevalence of dental caries, the type of self-care remedies utilized, and normative needs assessment among rural adults residing in Jeelugumelli Mandal, West Godavari District, Andhra Pradesh, India. **Materials and Methods:** A cross-sectional survey was conducted among 800 adults by using a multi-stage random sampling technique in Jeelugumelli Mandal, West Godavari District, India. Data were collected using a pretested pro forma consisting of questionnaire-related demographics, traditional care, and clinical examination which was investigated by a single examiner to record caries experience (Decayed, Missing, and Filled Teeth [DMFT]) using WHO 1997 criteria. The data were analyzed using IBM SPSS Statistics, Version 20.0. Mann-Whitney *U*-test, Kruskal-Wallis, and Multivariate Linear Regression analysis tests were used and the level of significance was set at $P \leq 0.05$. **Results:** Mean DMFT value of the study population was 10.29 ± 4.806 and 33.4% of the subjects had used home remedies related to plant origin. The majority of the study population required surgical need (Extractions) with a mean value of 4.23 ± 5.553 and compared with unskilled workers, unemployed workers had 2.8 units higher chances of having caries ($R = 2.810$ confidence interval [CI] 1.876–3.744) while it was 5.031 units lesser for professionals in having caries ($R = -5.031$ CI [-4.16] – [-5.901]). **Conclusion:** Dental caries prevalence and normative needs for dental caries were high in the adult population residing in Jeelugumelli Mandal and most of the individuals are depending on self-care procedures to relieve pain.

INTRODUCTION

Different factors can influence dental caries prevalence including demographic, political, and socioeconomic factors.^[1-4] The common beliefs, customs, and practices related to health and disease, in turn, influence the health-seeking behavior of inaccessible rural communities. Despite remarkable worldwide progress in the field of diagnostics, curative, and preventive health, the rural people still live in isolation, in natural and unpolluted surroundings far away from civilization with their traditional values, customs, beliefs, and myth intact.^[5]

Research suggests that higher rates of oral diseases occur in rural areas where a lower number of dentists are available

which remains a major barrier to oral health-care access for rural village residents.^[6] Facing numerous barriers to oral health care, low-income rural residents often are forced to choose alternative strategies, forgo treatment, and/or use self-care remedies for the relief of dental pain.^[7] Self-care is the component of health self-management that includes behaviors undertaken to enhance health, prevent disease, limit illness or restore health, which is derived from the individual's knowledge and skills.^[8] Given the large number of rural people who may seek pain relief by means other than visiting a

dentist, it is important to understand the “alternative” treatment methods or self-care they utilize for pain relief.^[9]

With this background, the present study was aimed to assess the prevalence of dental caries, type of self-care remedies utilized and normative needs among rural adult people residing in Jeelugumelli Mandal, West Godavari District, Andhra Pradesh, India. This study location is the border area between Andhra Pradesh and Telangana states of India.

MATERIALS AND METHODS

A population-based cross-sectional survey was conducted among people residing in a rural locality of a state in south India. Jeelugumelli, a rural Mandal (administrative division), was selected for analysis in the present study. It is one of the 46 mandals of the West Godavari district in the south Indian state of Andhra Pradesh and the demography of the selected mandal represents the typical rural population of southern India. A total of 800 subjects were selected by using multi-stage random sampling technique and the adult rural population of Jeelugumelli Mandal was divided into three age groups, i.e., (a) 18–27 years (b) 35–44 years (c) 65–74 years to document the age-group-wise variation in the profile of dental caries. Through multi-stage random sampling technique, 8 villages from the Jeelugumelli mandal were included in the present study. From the selected villages every alternate house was considered randomly and all the individuals present at the time of examination, falling in the specified age groups were included. The area for conducting examinations was planned and arranged for maximum efficiency and ease of operation. The subjects were allowed to sit on a chair or stool as per availability, where, sufficient natural daylight was available while avoiding discomfort from direct sunlight on either the subject or the examiner. A table to place instruments and supplies was placed within easy reach of the examiner. The recording clerk was allowed to sit close enough to the examiner so that instructions and codes could be easily heard and the examiner could see that findings were being recorded correctly.

Individuals who were non co-operative, mentally challenged, edentulous were excluded. The present study was conducted during 2017 for 4 months (June–September) and data collection was done using a specially designed pretested proforma consisting of two parts. The first part included information on demographic data and questions related to the utilization of traditional remedies. The second part included clinical examination by a single examiner who was trained and calibrated by a standard examiner to record caries experience (Decayed, Missing and Filled Teeth [DMFT]) using WHO 1997 criteria. Before the field study, the questionnaire validity was accomplished through the revision of the questionnaire by two senior experts in Public Health Dentistry and the revised questionnaire was subjected to a pilot study on 20 individuals for evaluating the psychometric properties. The intra-examiner reliability was measured by

repeated examinations performed on rural adults to assess the intra-examiner agreement of caries experience, using Cohen’s Kappa statistics. The intra-examiner reliability in recording the caries experience was 0.8 and 0.9, respectively.

Sample size estimation

The sample size was estimated based on the prevalence of dental caries determined through the National Oral Health Survey and Fluoride Mapping, India, 2003.^[10] In that survey, the prevalence of dental caries above 18 years was 70%. As dental caries is the most prevalent disease, the least percentage of caries prevalence (50%) was taken to get the maximum sample size. Based on the prevalence the sample size was calculated using the formula

$$\text{Sample size } (n) = (Z\alpha + Z\beta)^2/d^2$$

Ethical clearance and consent

Ethical clearance was obtained from the ethical committee of the SIBAR institute of dental sciences. The study protocol was later approved by the Dr. NTR University of Health Sciences (Pr. 37/IEC-SIBAR/CIR/15), Vijayawada, Andhra Pradesh, India, and voluntary written informed consent was obtained from all the individuals participating in the study before examination after discussing in detail about the purpose of the study.

Statistical procedures

The collected data were analyzed using IBM SPSS Statistics for Windows, Version 20.0. Armonk, NY, USA: IBM Corp.^[11] Descriptive and inferential statistics were used to summarize the results and tests such as the Mann-Whitney *U*-test, Kruskal-Wallis, and Multivariate Linear Regression were used. The level of significance was set at $P \leq 0.05$.

RESULTS

The mean DMFT value of the study population was 10.29 ± 4.806 and was highest among 64–75 years age group (12.79 ± 4.265) followed by 35–44 years (10.20 ± 4.284) and 18–27 years age group (6.40 ± 3.483) which is statistically significant ($P \leq 0.001$). Mean DMFT values were higher among unemployed (17.25 ± 4.494), unskilled workers (11.40 ± 3.896) compared to skilled (4.54 ± 0.503), clerical/shop owner (8 ± 0.001), and professionals (5.02 ± 4.075) which is statistically significant ($P \leq 0.001$) [Table 1].

The majority of the study population required surgical need (Extractions) with a mean value of 4.23 ± 5.553 followed by prosthetic need (4.12 ± 1.337), pulp care and restorations (2.66 ± 3.349), one surface filling (2.18 ± 2.145), two surface fillings (1.29 ± 1.595). Mean surgical need (10.07 ± 4.067), and prosthetic need (9.80 ± 4.320) were higher for the 64–75 years age group [Table 2]. 33.4% of the subjects had been using home remedies related to plant origin for the treatment of dental caries and it was higher among 64–75 years age group (56%) [Graph 1]. Lack of financial support (50.8%) and decreased accessibility to the

dentist (14.6%) were the two main reasons for not consulting dentists for the treatment of dental caries [Graph 2].

Kruskal-Wallis test, ^{*}Statistically significant. SD: Standard deviation

Compared with unskilled workers unemployed workers had 2.8 units higher chances of having caries ($R = 2.810$ confidence interval [CI] 1.876–3.744) while it was 5.031 units lesser for professionals in having caries ($R = -5.031$ CI [-4.16] – [-5.901]). Compared to the 64–75 years age group, the 18–27 years age group had 7.196 units lesser chances of having caries ($R = -7.196$ CI [-7.780] – [-6.612]), while it was 4.164 units lesser for 35–44 years age group. Compared to the lower middle class, the upper-middle class had 11 units lesser chances of having caries ($R = -11.102$, CI [-12.097] – [-10.17]) while it was 5.192 units lesser for the upper-middle class [Table 3].

DISCUSSION

Despite its known multifactorial etiology and prevention possibility, dental caries still represents the most widespread disease in the world, affecting various populations at different age groups.^[12,13] The current study was executed among rural areas of Jeelugumelli Mandal where there are various influential factors responsible for the higher prevalence of dental caries. As a result, these subjects are forced to use nontraditional providers to forgo treatment or use alternative strategies or self-remedies for the relief of dental pain.

In the present study, there was preponderance in male participation compared to females which was in accordance with Pashayev *et al.* The traditional patriarchal norms and limited education have relegated women to secondary status within the society could be the reason behind the less participation of females.^[3,14] Males had higher caries experience compared to females which was in contrast with the study done by Shaffer *et al.* Females are more concerned for esthetics and consume fewer amounts of refined sugars compared to males, which could be the reason for less caries in them in the present study.^[15-18]

There is an increase in mean DMFT values with an increase in the age which is in accordance with Kamberi *et al.* The decayed component was higher among 35–44 years age

*Statistically significant. OR: Odds ratio, CI: Confidence interval

group, missing component was higher for 65–74 years, and filled component was comparatively higher for 18–27 years age group which are in accordance with Pashayev *et al.*^[19] An increase in age directly increases the exposure to a cariogenic environment might be a reason for increased DMFT levels in the present study.^[20]

Individuals suffering from dental caries do not always seek relief by visiting a dentist. For individuals who have low income who do not seek treatment from a dentist self-care plays a palliative role.^[7] 79.6% of the study participants had utilized at least one type of self-care to overcome the painful experience.^[21] 21.5% of Respondents more frequently reported using nonprescription medicines or over-the-counter medication for pain relief and this in-contrast with the findings of Locker D *et al.* where most of the participants received care from the dentist.^[22] The frequent use of nonprescription medicines suggests that there is a need for a greater understanding of how rural people learn about the effectiveness and safety of nonprescription medications.

Home remedies of plant origin are used by the majority of respondents to get relief from oral pain. According to the respondents, the sap which is coming out from the barks of *Jatropha Gossypifolia* will relieve the teeth as well as gum pain. This finding is in agreement with a study done by S Ganesan.^[23]

The plant's *Jatropha curcas* Linn (called “*mepala*” in telugu), *Jatropha Gossypifolia* Linn (called “*chima mepala*”) belonged to Euphorbiaceae family. The young stem, latex of these plants

Graph 2: Age group-wise distribution of subjects based on barriers for not visiting the dentist

are used to get relief from teeth pain, fetid smell, mouth, and gum ulcers.^[24] Along with these plants, *Andrographis paniculata* (green Chirayta in English language, *Nelavemu* in the Telugu language) is also being used by natives for relief of tooth pain which is naturally grown in Jeelugumelli environmental conditions.^[21]

Regarding the normative needs of the population, the majority need extractions as a treatment option for dental caries followed by prosthetic need, pulp care, two surfaces, and one surface filling respectively. These findings are in disagreement with the study done by Maru *et al.*, Duraiswamy *et al.*, where there is a major need for one surface filling. The need for extractions and replacement of missing teeth are higher among the 65–74 years age group, while pulp care and restorations were higher among 35–44 years age group.^[3,25]

While the effect of sociodemographic factors on oral health and dental care-seeking behavior has been well characterized in developed countries, this is not the case in developing countries.^[26] Compared to developed countries, the limited number of oral health care institutions and the less coverage of community oral health services combine to compromise access to oral health care services in India.^[26] In addition, health insurance coverage is higher in urban areas compared to rural areas in India. Furthermore, medical insurance is not nationalized, and coverage is mainly provided by employers. As a result, many patients have to pay for oral health care themselves.^[26] These prospects explained well the reasons for accumulated needs among elderly age groups compared to younger age groups.

Limitations

1. The cross-sectional design of the study inherits a limitation; it does not allow the determination of a causal relationship between the variables investigated and the outcome
2. Though a short time frame was used, recall bias was inevitable.

CONCLUSION

The high prevalence of dental caries found in the adult population residing in Jeelugumelli mandal should be

considered a relevant dental public health problem. Most of the individuals are depending on their self-care procedures to relieve pain and there is a high accumulation of normative needs in the current population.

Recommendations

1. Additional research to explore the safety and effectiveness of plant *Andrographis Paniculata* which has an immense significance in treating medical conditions is recommended for its application in treating dental pain
2. Dental doctors should be appointed in primary health centers along with medical staff to reduce the accessibility barrier in the utilization of dental services among rural residents
3. Should work on mobile and portable dental services through a public-private partnership among inaccessible areas
4. Additional advanced research like phytochemical analysis on self-care medicinal plants should be encouraged to rule out its safety and efficacy in treating dental diseases.

Antiplaque Efficacy of Toothpaste – A Systematic Review and Meta-analysis of Randomized Controlled Trials

Sneha Nachu, Srinivas Ravoori, Srinivas Pachava

Department of Public Health Dentistry, SIBAR Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Background: Different toothpastes of the corresponding active ingredients could have variable extent of effectiveness; this raises the amount of choices with the marketplace for toothpaste containing these agents and makes it more difficult to gauge their effectiveness. Therefore, the purpose of this systemic review and meta-analysis was to gauge the antiplaque efficacy of different toothpaste agents in studies involving randomized clinical trials published over a span of January 2015-May 2020. **Materials and Methods:** A comprehensive and systematic electronic search via PubMed, TRIP, Cochrane, and Google scholar prompted in 593 articles. Subsequently screening titles and abstracts for applicability, 31 Randomized controlled trial (RCT) articles were enclosed in the review. With the aid of the Cochrane Collaboration's tool, the risk of bias of each study was assessed. **Results:** A total of 2467 individuals partake in 31 RCT studies. Triclosan toothpaste was superior over sodium fluoride/monofluorophosphate toothpaste (standard mean difference, SMD – 1.36, 95% confidence interval [CI] (2.81–0.10), $P = 0.007$) in plaque reduction. Long-term utilization of stannous fluoride toothpastes reduced dental plaque superior than monofluorophosphate toothpaste (SMD – 0.61, 95% (CI 1.04–0.18), $P = 0.005$). There was no discernible difference in plaque reduction. **Conclusion:** Within the confines of the current study's limitations (which embody the severe imbalance within the quantity of evidence), once scrutiny among products, triclosan and stannous fluoride in dentifrices seem to be the foremost efficacious plaque controlling active agents.

Keywords: Antiplaque efficacy, randomized controlled trial, toothpaste

INTRODUCTION

Dental plaque is a biofilm harboring innumerable microorganisms and is a requisite factor for the inception and furtherance of periodontal diseases.^[1] The pioneer cariogenic microorganisms strains present in the plaque are the strains of *Streptococcus mutans*. They bring about alterations in the plaque metabolism, causing demineralization to predominate. Interruption of dental biofilm by mechanical debridement is pivotal to overseeing plaque and gingivitis. The two standard compelling techniques are mechanical plaque and chemical plaque control.^[2]

One of the most quintessential oral hygiene care strategies is to use a toothbrush in conjunction with a dentifrice to limit plaque accumulation and the risk of plaque-related diseases, including periodontitis and caries.^[3] Microbial infections are liable for a substantial percentage of dental problems. Dental issues are predominantly of development of dental plaque, dental caries, and periodontal diseases.^[4]

Different components have been incorporated as active ingredients in toothpaste concoctions, pertaining to the therapeutic claim.^[5] Contingent upon their activity, they can be assorted as antimicrobial, plaque inhibitory, antiplaque, or anti-gingivitis. Antiplaque agents are those able to impinge gingivitis and plaque significantly, and they ought to be favored in the therapeutics of gingivitis and the interception of periodontal diseases.^[6]

The precise formulation of the active agents into toothpaste is essential to maintain the agents' bioaccumulation and, in certain instances, to amelioration their substantivity. Thus, different concoctions of the corresponding active ingredients may have varying extent of effectiveness, this

raises the number of options in the marketplace for products containing these agents and makes it more difficult to gauge their effectiveness.^[7] Therefore, the purpose of this systemic review and meta-analysis was to gauge the antiplaque efficacy of different toothpaste agents in studies involving randomized clinical trials published over a span of January 2015–May 2020.

MATERIALS AND METHODS

Framing of a research question and protocol registration

Using the PICO plan, the pursuit technique was done by an inquiry mirroring the point of the investigation: “what is the comparative efficacy of various toothpastes on the reduction of dental plaque in different groups of the population?”

Protocol registration: CRD42021246121 (<https://www.crd.york.ac.uk/prospero/#myprospero>).

Search strategy

The search was confined to randomized controlled trial (RCT) articles published from 2015 until 2020. This data confinement was preselected due to the rapid advancement of new toothpaste formulations. A comprehensive and systematic electronic search via PubMed, TRIP, Cochrane, and Google scholar using combinations of keywords antiplaque, efficacy, toothpaste, dentifrices, plaque resulted in 593 articles. Two reviewers removed duplicates from emanate obtained and independently scrutinized the remaining articles in terms of title and abstract. Subsequent to screening titles and abstracts for applicability, 31 RCT articles were enclosed in the review [Figure 1].

Inclusion criteria

- Research limited to RCTs
- Articles published in English
- Articles published within the span of 5 years, i.e., 2015-2020
- The publications which were available as full reports
- Studies conducted in any country on the general population with no restrictions on age and gender.

Exclusion criteria

- *In vitro* studies, abstracts, case reports, pilot studies, narrative reviews, and letters to editors were excluded.

Assessing the quality of the included studies

An aggregate of 31 articles have been chosen per the defined criteria. All the 31 articles were assessed with respective CONSORT checklists. With the aid of the Cochrane Collaboration tool, the risk of bias of each study was evaluated. Cochrane Review Manager Version 5.4 was used to generate risks of bias figures.

Statistical analysis

Cochran's Q coefficient, a Chi-square test, and a significance cutoff of 10% were used to determine the data's heterogeneity. For continuous data, a random-effects model was accustomed to combine the primary outcome variables from each study.

To assess the consistency of the results, the I² statistic and forest plots were employed. Overall outcome were assessed as standardized mean differences (SMD) (95% confidence interval [CI]). Review manager (RevMan), version 5.4.1 for Windows, The Cochrane Collaboration, Copenhagen, Denmark has been used to analyze data.

RESULTS

A total of 2467 individuals took part in 31 RCT studies. A conspectus of the selected studies and their characteristics is presented in Table 1.

Study design and subject characteristics

The proportions of researches conducted using parallel and cross-over designs were 90% and 10%, respectively. Only one study^[31] was triple blinded, 17 studies^[8,9,11-14,21,22,24,26,28-30,32,34-36] were double blinded, four studies^[7,16,23,37] were single blinded, whereas nine studies^[10,15,17-20,25,27,33] had not mentioned blinding. Twenty-eight studies were organized in clinical settings with adult participants, while in contrary two studies^[10,20] included children as participants and one study^[8] with dental students.

Risk of bias

The quality assessment is depicted in Figure 2.

For random sequence generation, no bias was ascertained. Blinding of personnel and participants, as well as incomplete outcome data, showed a substantial risk of bias more than 75%. Blinding of outcome assessment and allocation concealment disclosed a >50% unclear risk of bias 26% low-risk bias was seen for selective reporting [Figure 2].

Interventions and regimens

Out of 31 studies, 16 were herbal interventions, four were Triclosan interventions, three were stannous fluoride interventions, two were Probiotics interventions, two were plaque indicating dye interventions, and one was chlorhexidine intervention. Out of 16 herbal intervention studies, 11 studies were compared with conventional toothpaste. In all the studies, manual toothbrushes were used. Most of the researches forbade the utilization of any auxiliary oral hygiene practice.

Meta-analysis

As the outcome evaluation methods were different and there was a loss of quantitative data, only 18 articles were included in the meta-analysis. Triclosan toothpaste was superior over sodium fluoride/monofluorophosphate toothpaste (standard mean difference [SMD] -1.36 , 95% CI (2.81–0.10), $P = 0.007$) in plaque reduction [Figure 3]. Long-term use of stannous fluoride toothpastes reduced dental plaque superior than monofluorophosphate toothpaste (SMD -0.61 , 95% CI 1.04–0.18), $P = 0.005$) [Figure 4]. There was no significant difference (SMD -0.38 , 95% CI -0.82 , -0.06), $P = 0.009$) in plaque reduction between herbal and conventional toothpaste [Figure 5].

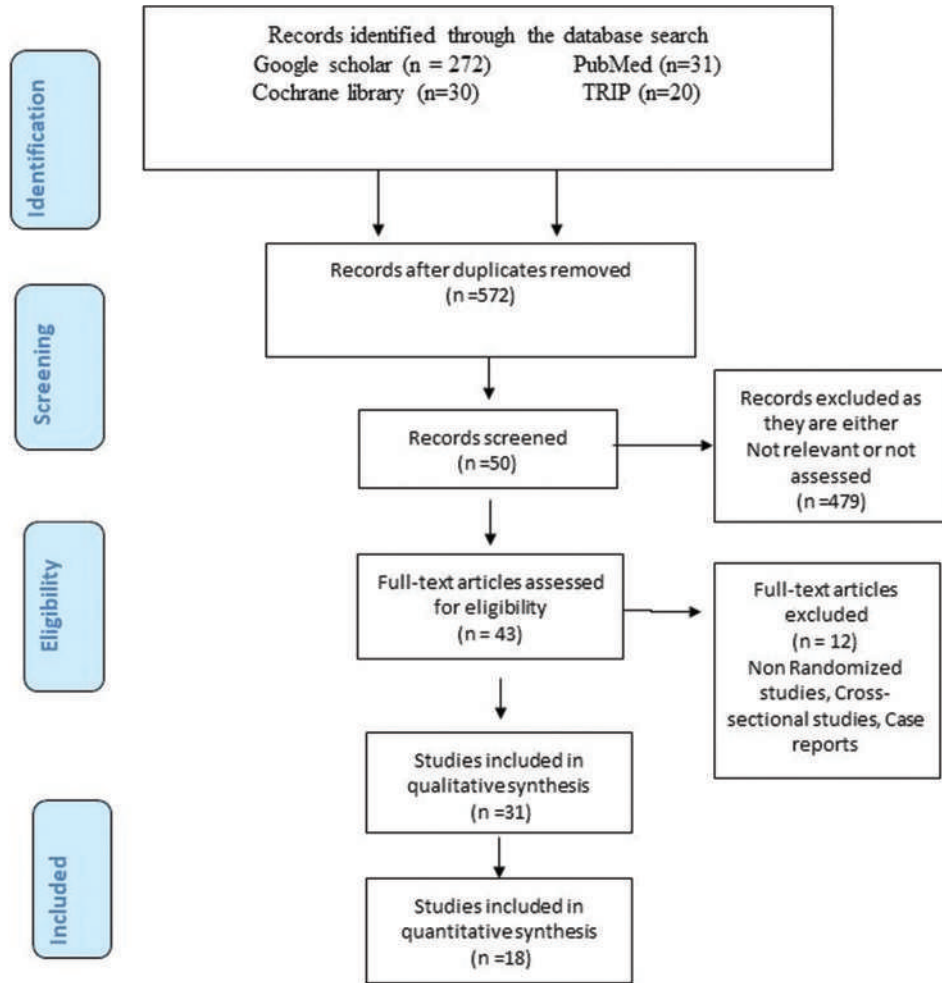

Figure 1: PRISMA flow diagram

Figure 2: Risk of bias graph and summary: review authors' judgments about each risk of bias item presented as percentages across all included studies

Dr. L. KRISHNA PRASAD

Table 1: An overview and characteristics of included studies

Year, author, and project location	Duration of study	Intervention/comparison	Statistical inference	Conclusion/recommendation
2015 Abhishek <i>et al.</i> ^[8] Karnataka, India	30 days	Conventional toothpaste (<i>n</i> =15) versus neem containing toothpaste (<i>n</i> =15)	<i>t</i> -test <i>P</i> =0.001	Within the limitations (small sample size and Hawthorne effect), regular use of neem containing toothpaste provided a significant reduction of participants' dental plaque
2015 Mitra <i>et al.</i> ^[9] Mumbai, India	4 weeks	Herbal toothpaste (<i>n</i> =50) versus triclosan-containing toothpaste (<i>n</i> =50)	<i>t</i> -test <i>P</i> >0.05	Herbal toothpaste is equally efficient in the control of plaque as triclosan-containing toothpaste
2016 Sälzer <i>et al.</i> ^[10] Netherlands	8 weeks	Colgate caries protection toothpaste (without SLS, <i>n</i> =57) versus Zendium classic toothpaste (with SLS, <i>n</i> =58)	ANCOVA independent <i>t</i> -test paired <i>t</i> -test <i>P</i> =0.690	No statistically significant difference in plaque scores between the control group (with SLS) and the test group (SLS)
2015 Bayoumi <i>et al.</i> ^[11] Egypt	3 months	Colgate total containing sodium fluoride and 0.3% triclosan (<i>n</i> =25) versus Colgate max fresh containing 0.22% sodium fluoride (<i>n</i> =25)	Chi-square Mann-Whitney Friedman test Wilcoxon signed ranks test <i>P</i> =0.001	Triclosan toothpaste proved to have marked antiplaque and antigingival effect
2017 Tadikonda <i>et al.</i> ^[12] India	1 month	Colgate healthy teeth toothpaste (<i>n</i> =25) versus Glodent dentifrice containing papain, bromelain, neem, and miswak with 1000 ppm fluoride (<i>n</i> =25)	Paired <i>t</i> -test independent <i>t</i> -test <i>P</i> <0.001	Significant reduction in plaque score in the test (golden dentifrice) group compared to the control group (Colgate healthy teeth toothpaste)
2015 Ayad <i>et al.</i> ^[13] Canada	4 weeks	Toothpaste containing triclosan, PVM/MA polymer and 0.243% sodium fluoride i.e., Colgate total advanced whitening toothpaste (<i>n</i> =55) versus toothpaste containing 0.76% of sodium monofluorophosphate i.e., Colgate cavity protection toothpaste (<i>n</i> =60)	Independent <i>t</i> -test paired <i>t</i> -test <i>P</i> <0.05	The test regimen has significantly greater efficacy in controlling established dental plaque and gingivitis than the negative control regimen
2016 Liu and Yin ^[14] China	12 weeks	Toothpaste containing 0.6% <i>Ilicis Rotundae</i> cortex in a calcium carbonate base (<i>n</i> =25) versus toothpaste without any active ingredients (<i>n</i> =25)	Chi-square Paired <i>t</i> -test <i>P</i> <0.01	0.6% <i>Ilicis Rotundae</i> cortex was effective in reducing plaque compared to toothpaste without any active agents
2015 Shanmugapriya <i>et al.</i> ^[15] India	72 h	Herbal toothpaste (<i>n</i> =15) versus commercially available toothpaste (<i>n</i> =15)	Unpaired <i>t</i> -test paired <i>t</i> -test <i>P</i> =0.001	Plaque inhibitory action of herbal toothpaste was marginally less when compared to commercial toothpaste
2016 Stevens <i>et al.</i> ^[16] USA	7-10 days	Toothpaste without plaque indicating dye (<i>n</i> =20) versus toothpaste with a plaque indicating dye (<i>n</i> =20)	Paired <i>t</i> -test Independent <i>t</i> -test <i>P</i> =0.03	Mechanical plaque removal brushing with toothpaste containing plaque indicating dye showed significantly reduced plaque than toothpaste without dye
2017 Mina <i>et al.</i> ^[17] Iran	12 weeks	Masdent toothpaste containing <i>Pistacia lentiscus</i> (<i>n</i> =30) versus crest complete toothpaste (<i>n</i> =30)	ANCOVA Mann-Whitney <i>U</i> -test Wilcoxon test <i>P</i> =0.855	The Masdent group has higher plaque reduction efficacy than the crest group, which was not statistically significant
2017 Singh ^[18] Jammu, India	6 weeks	Herbal toothpaste (<i>n</i> =65) versus Colgate sensitive toothpaste (<i>n</i> =65)	<i>t</i> -test Chi-square test <i>P</i> >0.05	Both the dentifrices are equally effective in controlling plaque
2017 Arabsolghar <i>et al.</i> ^[19] Iran	14 days	Crest anti-cavity (without chlorhexidine, <i>n</i> =10) versus kin gingival (with chlorhexidine, <i>n</i> =10) versus orthokin (with chlorhexidine and zinc acetate, <i>n</i> =10)	ANOVA <i>P</i> >0.05	Orthokin had a greater but no significant antiplaque effect than kin gingival and crest toothpaste
2017 Sangeetha ^[20] India	30 days	Triclosan-containing toothpaste (<i>n</i> =28) versus fluoride-containing toothpaste (<i>n</i> =28)	Independent <i>t</i> -test paired <i>t</i> -test <i>P</i> =0.001	Triclosan-containing toothpaste significantly reduced plaque compared to conventional fluoride toothpaste
2017 Arat Maden <i>et al.</i> ^[21] Turkey	6 weeks	Xylitol (<i>n</i> =16) versus xylitol probiotic (<i>n</i> =16) versus fluoride dentifrice (<i>n</i> =16)	Kruskal-Wallis Mann-Whitney <i>U</i> -test <i>P</i> =0.006	Probiotic toothpaste showed statistically significant plaque reduction compared to xylitol and fluoride toothpaste groups with a 6 weeks follow-up period

Table 1: Contd...

Year, author, and project location	Duration of study	Intervention/comparison	Statistical inference	Conclusion/recommendation
2018 Hosadurga <i>et al.</i> ^[22] Karnataka, India	28 days	Colgate herbal toothpaste (<i>n</i> =20) versus parodontax (<i>n</i> =25)	<i>t</i> -test Chi-square test <i>P</i> <0.001	Significant reduction in the test and control groups' plaque score within the limitations (small sample size, sampling frame may not represent the general population and dropouts in the control group)
2018 Rusminah <i>et al.</i> ^[23] Indonesia	7 days	Miswak toothpaste (<i>n</i> =15) versus non-Miswak toothpaste (<i>n</i> =15)	Paired <i>t</i> -test <i>P</i> =0.01	Toothpaste containing Miswak was more effective in reducing plaque compared to non-Miswak toothpaste
2019 Daly <i>et al.</i> ^[24] UK	3 months	Toothpaste containing enzymes and proteins i.e., Zendium-1450 ppm sodium fluoride, lactoferrin, lactoperoxidase, colostrum, amyloglucosidase, glucose oxidase, and potassium thiocyanate (<i>n</i> =113) versus Sensodyne Pronamel – sodium fluoride 1450 ppm (<i>n</i> =116)	Independent <i>t</i> -test paired <i>t</i> -test <i>P</i> =0.01	Toothpaste containing enzymes and proteins had efficacy in reducing plaque compared to the control group
2018 Rangrej <i>et al.</i> ^[25] India	15 days	PatanjaliDantKanti (<i>n</i> =17) versus Colgate herbal (<i>n</i> =17)	Independent <i>t</i> -test Paired <i>t</i> -test <i>P</i> =0.016	Within the limitations (small sample size, short duration of the study), the study concluded that the regular use of these herbal dentifrices significantly reduced the plaque accumulation and improved the participants' gingival health
2019 Hu <i>et al.</i> ^[26] China	6 months	0.457% stannous fluoride stabilized zinc phosphate in a silica base (<i>n</i> =49) versus 0.76% sodium monofluorophosphate in a phosphate dehydrate base (<i>n</i> =49)	Independent <i>t</i> -test Chi-square test <i>P</i> <0.001	The test group significantly reduces plaque compared to the control group as stannous fluoride acts as an antimicrobial agent
2019 Lorenz <i>et al.</i> ^[27] Germany	12 weeks	Monofluorophosphate (<i>n</i> =120) versus. amine fluoride/stannous fluoride (<i>n</i> =120)	Unpaired <i>t</i> -test <i>P</i> <0.001	The test group (amine fluoride/stannous fluoride) showed a statistically significant reduction in plaque score than the control test group (monofluorophosphate)
2018 Menon <i>et al.</i> ^[28] Kerala, India	12 months	Calcium phosphate-containing toothpaste, (<i>n</i> =15) versus calcium sucrose phosphate toothpaste (<i>n</i> =15)	ANOVA Student's <i>t</i> -test <i>P</i> =0.044	Significant reduction (<i>P</i> =0.044) in the plaque amount in calcium sucrose phosphate toothpaste group compared to calcium phosphate-containing toothpaste group
2019 Pentapati <i>et al.</i> ^[29] Bangalore, India	One month	100 ppm fluoridated toothpaste, i.e., Colgate, (<i>n</i> =38) versus herbal nonfluoridated toothpaste, i.e., Sudanta toothpaste, (<i>n</i> =37)	ANCOVA independent <i>t</i> -test paired <i>t</i> -test <i>P</i> <0.001	Significant decrease in mean plaque score in both the test (Sudanta Toothpaste) and control group (Colgate)
2019 Seriwatanachai <i>et al.</i> ^[30] Thailand	6 months	A regular fluoride toothpaste (<i>n</i> =45) versus crest pro-health, stannous fluoride with zinc lactate (<i>n</i> =45) versus Colgate total, stannous fluoride dentifrice with zinc phosphate (<i>n</i> =45)	ANCOVA Independent <i>t</i> -test Chi-square test <i>P</i> <0.001	Statistically significant efficacy of plaque control is seen in test dentifrice (stannous fluoride with zinc lactate) and commercial stannous fluoride-containing dentifrice
2019 Cheng <i>et al.</i> ^[31]	12 weeks	Pudilan extract containing toothpaste (<i>n</i> =59) versus Pudilan toothpaste simulator (<i>n</i> =55)	Chi-square Group <i>t</i> -test <i>P</i> <0.01	The Toothpaste containing Pudilan extract could effectively control plaque and can improve and prevent chronic gingivitis
2019 Koshy <i>et al.</i> ^[32] India	10 days	Patanjali Dant Kanti (<i>n</i> =15) versus Colgate dental cream (<i>n</i> =15)	Paired <i>t</i> -test Mann-Whitney <i>U</i> -test <i>P</i> =0.016	Within the limitations (short duration for the course, the tooth brushing technique's credibility, and toothbrush) concluded that herbal toothpaste has significantly higher plaque scores than conventional toothpaste
2019 Valones <i>et al.</i> ^[33] Brazil	1 month	<i>Rosmarinus officinalis</i> Linn. (<i>n</i> =55) versus Colgate-Palmolive (<i>n</i> =55)	Wilcoxon test <i>P</i> >0.005	<i>Rosmarinus officinalis</i> was effective in controlling plaque when compared to conventional fluoridated

Year, author, and project location	Duration of study	Intervention/comparison	Statistical inference	Conclusion/recommendation
2019 Singh <i>et al.</i> ^[34] India	30 days	Dant kanti (<i>n</i> =19) versus Colgate total (<i>n</i> =19)	Independent <i>t</i> -test Paired <i>t</i> -test <i>P</i> =0.315	Within the limitations (shorter duration of the experiment), the study concluded that clinically herbal dentifrice is as effective as a nonherbal dentifrice in reducing plaque
2019 Cunha <i>et al.</i> ^[35] Brazil	18 weeks	0.3% triclosan, 2% copolymer and 0.243% sodium fluoride (<i>n</i> =25) versus BlueM group (hydrogen peroxide, sodium perborate, honey, xylitol, and lactoferrin (<i>n</i> =25)	ANOVA Mann–Whitney <i>U</i> -test <i>P</i> >0.005	The toothpaste containing oxygen and lactoferrin have comparable efficacy in controlling plaque as triclosan-containing toothpaste
2019 Shenoy and Prabakar ^[36] India	15 days	Toothpaste without plaque indicating dye (<i>n</i> =10) versus toothpaste with a plaque indicating dye (<i>n</i> =10)	Wilcoxon signed rank test Mann–Whitney <i>U</i> -test <i>P</i> =0.002	Regular use of plaque indicating dye-containing toothpaste significantly increases plaque removal efficacy
2020 Ramesh <i>et al.</i> ^[37] India	60 days	Herbal-based commercial toothpaste (<i>n</i> =20) versus homeopathic-based commercial dentifrice (<i>n</i> =20) versus conventional dentifrice (<i>n</i> =20) versus prepared placebo dentifrice (<i>n</i> =20)	ANOVA <i>P</i> =0.001	Herbal dentifrices have equivalent efficiency to conventional dentifrice in plaque reduction
2020 Kaur <i>et al.</i> ^[38] India	45 days	No intervention continued to use the same toothpaste (<i>n</i> =15) versus probiotic toothpaste (<i>n</i> =15)	One-way ANOVA Paired <i>t</i> -test <i>P</i> <0.01	Statistically significant reduction in plaque in both the groups

P<0.05 – Statistically significant. SLS: Sodium lauryl sulfate, PVM/MA: Polyvinyl methyl ether/maleic acid

DISCUSSION

Although the fact that most populace assert to brush their teeth at least once daily, gingivitis and chronic periodontitis are still pervasive in the majority of the population. Maintaining an adequate degree of plaque control with conventional mechanical procedures and dentifrices is manifestly challenging; nonetheless, it is presently the sole realistic means of enhancing community periodontal health from a preventive standpoint.^[28] In an attempt to find answers for clinical enquires, it is necessary to conduct an evidence-based literature search.

The active ingredients in the herbal dentifrices used in the present systematic review are myrrh, sage, chamomile, eucalyptus, essential oils, 4% Tulsi extract, 0.6% *Ilicis Rotundae* cortex, *Pistacia lentiscus*, papain, bromide, miswak, and neem acts by penetrating the biofilm, resulting in disruption of plaque and has antibacterial properties. There is substantiation that herbal dentifrices may be efficacious toward dental plaque, so one would anticipate accord on which dentifrice to choose. The review enclosed eleven randomized control trials encrusting a total populace of 703 qualified for the assessment of mean plaque depletion. The presence of predisposition in 11 enclosed studies, three of which had a low risk of bias, can be attributed to the existence of heterogeneity. Apart from blinding of participants and personnel, which showed a low risk of bias across all studies, all domains demonstrate a high risk of bias. None of the studies have a follow-up period of >3 months. With a high *I*² esteem (*I*² = 87%), the results of various studies can be inconclusive. The estimates favored neither herbal nor

conventional dentifrices because the risk of predisposition was detected to be high and the methodological quality was identified to be low. Ultimately, there is inconsistency in documenting any adverse effects associated through use of exploratory herbal products. These findings are similar to the Mehta *et al.*^[39] (SMD 2.14; 95% CI: 0.88–3.41, *P* = 0.0009), which delineated there is no high-quality evidence supporting or contradict the herbal dentifrice's antiplaque efficacy.

There was moderate quality evidence that toothpastes containing triclosan/copolymer with fluoride reduced plaque in comparison to fluoride toothpastes that did not contain triclosan/copolymer (SMD 1.36, 95% CI (2.81–0.10), *P* = 0.007).

Although the findings of discrete trials in the meta-analyses exhibited significant heterogeneity, the SnF2 dentifrice performed better than other dentifrices (SMD –0.61, 95% CI (1.04–0.18), *P* = 0.005). The findings of the current research are consistent with those of the Johannsen *et al.*^[40] research which found that SnF2-containing dentifrices diminished dental plaque and gingivitis (SMD –0.63, 95% CI (1.11–0.15), *P* = 0.010).

The methods used to gauge the plaque vary widely across the included studies: 26.5% of researches used Silness and Loe plaque index (PI); 55.9% utilized Turesky–Gillmore–Glickman modification of Quigley–Hein PI; 5.9% of studies used MGMPI; 2.9% studies used O'Leary PI; 5.9% used Turesky–Gillmore–Glickman PI and 2.9% used image analysis, whereas a study done by Mitra *et al.* did not specify the type of plaque scoring index.^[8] Significant statistical heterogeneity due to

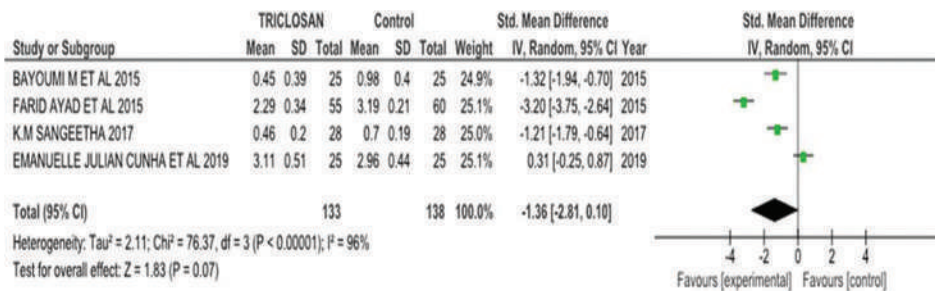

Figure 3: Forest plot of comparison: Triclosan versus control toothpaste

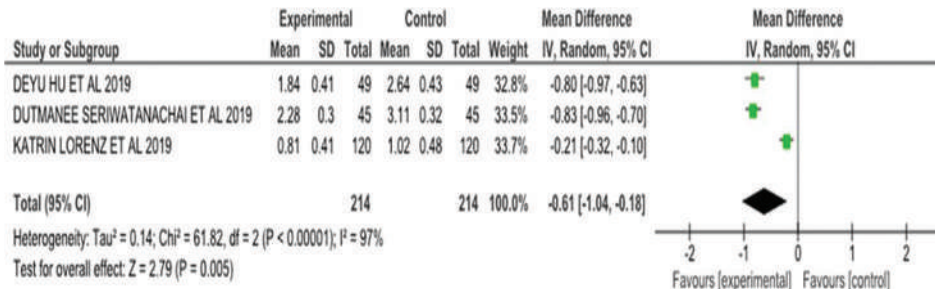

Figure 4: Forest plot of comparison: Stannous fluoride versus control toothpaste

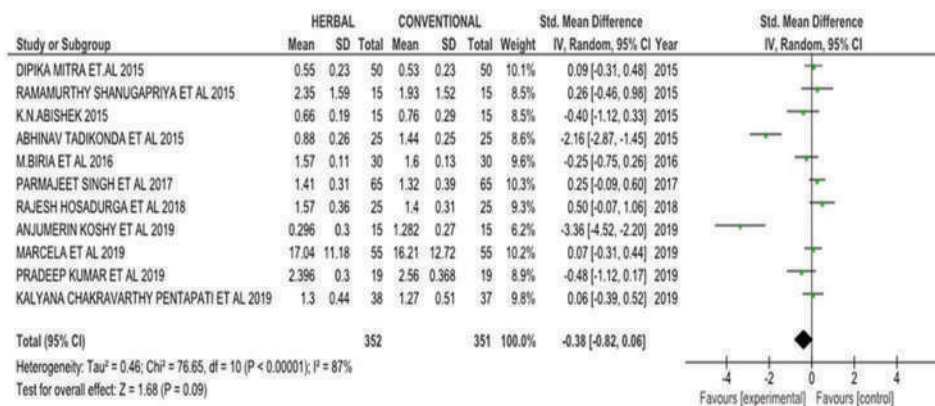

Figure 5: Forest plot of comparison: Herbal versus conventional toothpaste

methodological diversity in outcome assessment tools indicates that the researches are not all reckoning the same quantity, but it does not certainly imply that the actual intervention effect varies.^[41]

The majority of researchers (76.4%) did not use proper sample size calculations when enlisting the research populace. The findings of the meta-analysis may be influenced by the limited sample size. Apart from the toothpaste interference, the provisions were distinctive since various sorts of manual toothbrushes have been used, which may have contributed in an additional disparity in all of the research findings. Different concoctions of the test and control group have varying efficacy levels and would have affected intervention outcomes. Furthermore, a thorough review of the data revealed variations within the consistency of methodological

approaches, populace, and rate of attrition. About 17.8% of the study population was lost in follow-up, which could have influenced the study results.

Limitations of this review

The considerable variance in the quantity of researches collating each active agent and the various risks of bias necessitates caution when analyzing the results. A severe imbalance in the amount of evidence for each intervention may affect the overall analysis's power and reliability.

The implication for future research

Future RCTs evaluating auxiliary chemotherapeutics must include at least a 6-month follow-up period to establish the efficacy and safety of patients' chemical agents and compliance and compensate for the Hawthorne effect, with outcome measures assessed at baseline, 6 months, and an intermediate

time point. It is foremost to maintain a proper interpretation of the baseline clinical idiosyncrasy and periodontal diagnosis, as well as the pertinent outcome measures reported.

CONCLUSION

Within the confines of the current study's limitations (which embody the severe imbalance within the quantity of evidence and data confinement to time restraint), once scrutiny among products, triclosan and stannous fluoride in dentifrices seem to be the foremost efficacious plaque controlling active agents. The literature supporting the use of herbal-based antiplaque preparations is generally weak, since most observations suffered from a lack of experimental design and a dearth of pertinent controls and comparisons. It is critical to understand that, in the absence of a negative monitor, head-to-head distinctions with existing products with known competence are not an adequate experimental design.

ABSTRACT

Oral biofilms are a group of healthy synergistic organisms, that on interplay with the immune system undergo transition and colonize the pathogenic bacteria, leading to various diseases like dental caries, gingivitis, periodontitis and a few systemic conditions. Dental caries being the most common disease of the oral cavity, comprise a heterogeneous group of bacteria that can cause imbalance in the biofilm. Caries prevention has been in research for decades, where antibiotics, chemical biocides and fluoride-antimicrobial approaches have not been adequate for this multifactorial disease. In recent years, the major focus of caries prevention has been shifted to plaque-biofilm modification as an ecological approach that would prevent bacterial colonization. Saliva produces various natural antimicrobial peptides that can regulate biofilm modification. Synthetic production of antimicrobial peptides concentrates on selective elimination and a targeted approach towards cariogenic pathogens, precisely *Streptococcus mutans* (*S. mutans*). A search in Medline/PubMed, EBSCO and ScienceDirect databases on C16G2, antimicrobial peptides (AMPs) and *S. mutans*, using MeSH (Medical Subject Heading) terms was performed and papers published until 2020 were included for further evaluation. A total of eight articles written in English with available full texts were selected based on the search strategy. They included four publications on AMPs against *S. mutans* and another four articles on AMPs in caries prevention. This review focuses on C16G2 antimicrobial peptide and its potential to modify biofilm and inhibit the targeted bacteria causing dental caries.

Key words: Antimicrobial Peptides; *Streptococcus Mutans*; Mouthwashes; Dental Caries; Anti-Bacterial Agents

INTRODUCTION

Antibiotics, the epitome of “wonder drugs”, have a major role in the control and prevention of microbial infections, predominantly bacterial pathogens [1]. However, drug resistance, overuse and misuse are growing concerns in the

management of microbial diseases pushing the world on to the cusp of a post-antibiotic era, where formerly efficient treatment procedures have become inapplicable.

Antibiotics, despite having a significant role in modern medicine, have mostly failed to control

and/or prevent many infections due to drug resistance, accentuating the need for developing newer antimicrobial medication management [2]. Recently, antimicrobial peptides (AMPs) have been recognized as potential antibiotic substitutes because of their broad-spectrum killing activity, including the drug-resistant strains [3]. AMPs are genetically common molecules of innate immunity observed mainly within neutrophil granules and in epithelial cell secretions of skin and mucosal surfaces of mammals [4,5]. AMPs are small, amphipathic molecules that possess both hydrophilic and hydrophobic areas with variable amino-acid structure/length and an overall cationic charge [6].

Based on their secondary structures, they can be categorized into four different types: beta-sheet, alpha-helix, extended and loop [7]. These are versatile, highly specific antimicrobial compounds that have a broad range of antibacterial, antiviral and antifungal activity [8]. A healthy cluster of synergistic microbial organisms amalgamate to form an oral biofilm. Microbes in the oral biofilm interact with the host immune system and can colonize, which may lead to dental caries, gingivitis, periodontitis or spread to distant organs causing systemic conditions [9,10]. Dental caries, the most prevalent disease of dental structures, are considered to be a multifactorial disease with predominant pathogenic events lead by *Streptococcus mutans* (*S. mutans*) [11]. Cariogenic bacterial pathogens rapidly metabolize carbohydrates and subsequently produce organic acids and reduce plaque pH, which leads to demineralization of inorganic components of dental hard tissues and irreversible loss of tooth structure [12,13]. This substantiates the concept of endogenous, biofilm mediated disease where acidogenic/aciduric elements inhabiting the oral flora gain an ecological advantage over other species and interrupt the homeostatic balance in the plaque biofilm, ultimately leading to commencement of the disease process [12].

DISCUSSION

Antimicrobial Peptides

Research studies on prevention of caries are

ongoing for decades with multiple modalities such as various types of sodium fluoride and dental sealants. The motive of current research studies shifted to modification of oral ecology-plaque biofilm with a specific aim to prevent bacterial colonization. AMPs are an adverse group of molecules with exceptional antimicrobial features and a great capacity for controlling bacterial infections and altering biofilm environment [8]. AMPs demonstrate a net positive charge and a high ratio of hydrophobic amino acids allowing them to selectively bind to negatively charged bacterial membranes. The ability of AMPs to kill bacteria usually depends on their capability to interact with the bacterial membrane or cell wall [11]. They display a direct and rapid antimicrobial property that can be categorized into two basic groups: The disruptive mechanisms, which cause disruption of physiological integrity of microbial membrane and the membrane undisruptive mechanisms, which act on targets within the cell [5,13].

Independent of the proposed group, the initial interaction between the cationic AMPs and the negatively charged bacterial surface is electrostatic [14].

In most AMPs, the interaction between cationic residues of peptides and the negatively charged moieties of a bacterial membrane can form pores that obliterate the membrane integrity, facilitating targeted microbe lysis [11].

There are four classical models of disruptive mechanisms: (1) Toroidal; (2) Carpet; (3) Aggregate; and (4) Barrel. Lately, novel disruptive models or models indirectly related to membrane disruption have been defined. These models are as follows: (1) Disordered toroidal; (2) Membrane thinning/thickening; (3) Charged lipid clustering; (4) Non-bilayer intermediate; (5) Oxidized lipid targeting; (6) Anion carrier; (7) Non-lytic membrane depolarization; and (8) the Electroporation model [14].

In the case of undisruptive mechanism, they traverse the lipid bilayer without any destruction but destroy bacteria through prevention of intracellular functions [11]. The undisruptive mechanisms rely on AMP passage through the membrane as a result of a combination of characteristics including AMP sequence and composition of the membrane. A number of

cellular metabolism reactions are prevented, which ultimately leads to cell death. Two mechanisms of AMP cell entry have been described including a spontaneous membrane translocation or crossing as a result of a secondary AMP structure that drives permeabilization of the membrane [13,14]. After crossing the membrane, multiple intracellular sites like gene promoters and coding sequences, mRNA-binding sites, enzyme regulatory sites, and protein pre-folding sites can be targeted by AMPs. Inhibition occurs through impeding DNA transcription and/or RNA translation, or causing breakdown of metabolic pathways and cell death by poor protein folding [15].

The main distinctions between microbial and mammalian cells such as membrane composition, polarization, transmembrane potential and structural features protect mammalian cells against AMPs [6].

In contrast to the bacterial membrane, the cytoplasmic membrane of the mammalian cell is loaded with zwitterionic phospholipids, producing a membrane with neutral net charge [16,17]. Thus, hydrophobic interactions are the major promoter of mammalian cell membrane

and AMP interplay. In comparison, the electrostatic interactions between AMPs and bacterial membranes are stronger [5]. Furthermore, mammalian cell membranes, differ from microbial membranes in that they possess a large amount of cholesterol [16-18] and are suggested to decrease AMP activity by stabilizing the phospholipid bilayer [19]. Mammalian cells have a lower negative transmembrane potential between (-90 to -110 mV) in contrast to bacterial cells (-130 and -150 mV) [16,17,20]. Strong negative membrane potential in bacteria may likewise assist in selectivity of AMPs between bacterial and mammalian cells [16]. Apart from limited number of pathogens, most indigenous oral microorganisms are beneficial. Broad spectrum killing activity exhibited by the currently available AMPs disrupts the ecological balance of the indigenous microbiota leading to unidentified clinical implications [21,22]. Therefore, establishment of new narrow-spectrum treatments that can preserve the protective advantages of the normal microflora during therapy is essential [23]. Promising studies on AMPs against *S. mutans* are listed in Table 1.

Table 1: Antimicrobial peptide (AMP) studies against *Streptococcus mutans* (*S. mutans*)

Study outline and conclusion	Author(s)/year
Potent 1 antibiotic component Mutacin B-Ny266 is efficient against <i>S. mutans</i> identified in the oral cavity. Antibiotics targeted against microbes in dental plaque is a promising strategy for controlling pathogenic oral microbial flora.	Dufour et al. 2020 [24]
Inhibitory action against adhesion, virulence associated genes and enzymes of <i>S. mutans</i> was observed in pomegranate-derived AMPs; Pug-1, Pug-2, Pug-3 and Pug-4. Antimicrobial pathway of Pomegranate against carious pathogens occurs due to anti-adherence properties. Pomegranate AMPs are non-toxic to human keratinocytes.	Kokilakanit et al. 2020 [25]
Biochemical contents produced from <i>Hylarana guentheri</i> such as Temporin-GHc and temporin-GHd renders antimicrobial action against bacteria and fungi. The antimicrobial action is achieved by downregulating glucosyltransferases enzyme in <i>S. mutans</i> . Selective and targeted antimicrobial action against <i>S. mutans</i> occurs in the presence of human erythrocyte.	Zhong et al. 2019 [26]
STAMP molecules are Specifically Targeted AMP synthetic molecules prepared to render antimicrobial property with a specific target against a pathogen. C16G2 is a STAMP molecule prepared by the combination of the killing domain from the antimicrobial agent Novispirin G10 with a targeting domain from <i>S. mutans</i> pheromone. C16G2 is prepared to selectively act against <i>S. mutans</i> to render anti-carious action in oral cavity without disturbing non-pathogenic resident bacteria in oral flora.	Baker et al. 2019 [27]

Recently, an initiation of a targeted approach to manage oral microbial pathogenesis using a newer version of AMPs called specifically targeted antimicrobial peptides (STAMPs) was developed [22,28].

A typical STAMP molecule requires two functionally independent peptide domains, a killing moiety comprised of a non-specific AMP that can rapidly destroy bacteria, and a targeting moiety comprised of a species specific, high affinity binding peptide [28,29].

The two moieties are subsequently integrated through a small linker, producing a fusion AMP without detrimental changes in the independent functions of two domains [13]. The AMP dimers (fusion peptides) compounded as single linear molecules, frequently possess higher killing dynamics in comparison to their parental peptides [4]. Randomized clinical trial studies against cariogenic microbes and caries management are shown in Table 2.

Table 2: Randomized clinical trials on antimicrobial peptides and caries management/prevention

No.	Study hypothesis	Study findings, inference, & clinical relevance	Author(s)/year
1	Gaseous ozone effect on deep carious pathogens identified from incompletely excavated carious lesions was evaluated. In addition, Vascular endothelial growth factor (VEGF) from pulpal tissue, neuronal nitric oxide synthase and superoxide dismutase (SOD) was also investigated in this study	Gaseous ozone reduced microbial count of bacteria that includes lactobacillus. The levels of VEGF were higher in pulp tissue and SOD activity was lower in the study group than controls. The findings of the study confirmed that gaseous ozone has a biocompatible effect on pulpal tissue by rendering antimicrobial action	Krunić et al. 2019 [30]
2	Salivary human neutrophil peptide 1-3 (HNP 1-3) levels were compared in the study group with probiotic supplements and in the control group. The results of the study showed higher levels of salivary HNP 1-3 among caries resistant children than caries susceptible	<i>Lactobacillus paracasei</i> probiotics enhance HNP 1-3 temporarily with significant statistical correlation elevated <i>Lactobacillus</i> spp. counts. The study also showed reduced <i>S. mutans</i> but did not show statistical correlation	Wattanarat et al. 2015 [31]
3	Importance of salivary proteins adsorbed on enamel surface and its demineralization effect was evaluated	Surfaces of enamel coated with whole saliva, parotid saliva, dialyzed whole and dialyzed protein saliva showed significantly higher levels of protection than uncoated enamel. The parotid and whole saliva rendered better protective action than dialyzed saliva. The findings of the study denoted that ionic contents of saliva provide protection against acid related enamel demineralization	Martins et al. 2013 [32]
4	<i>S. mutans</i> adhesion to cellular surface inhibition was studied by plasmon resonance method using synthetic peptide (p1025) to residues of 1025-1044 adhesions	In-vivo study model on streptococcal adhesion investigation revealed prevention of recolonization of <i>S. mutans</i> but not <i>Actinomyces</i> spp. The results of the study confirmed that peptide molecules inhibited microbial adhesins and prevented colonization	Kelly et al. 1999 [33]

Specifically Targeted Antimicrobial Peptides Targeting *S. mutans*

As discussed earlier, *S. mutans* is considered the primary etiological agent of dental caries. It is well known that, absence of *S. mutans* has been associated with areas containing healthy dentition, while progressively increasing levels of *S. mutans* are found in regions of caries development [34]. A study had mentioned that patients with dental plaque consisting of small amounts of *S. mutans* are resistant to exogenous colonization from cariogenic organism which have shown reduction on dental caries [35]. Thus STAMPs aimed at *S. mutans* can serve as an alternative therapy in preventing dental caries. Development of resistance to AMPs may occur due to contributions from both bacterial cell changes and host tissue alterations which eventually lead to inability of the host to act against bacterial infections. The resistance of the oral bacteria in prolonged AMPs may occur due to changes occurring in the organism such as surface remodelling, biofilm pathogen alterations and host tissue changes like efflux pump mechanism of organisms and proteolytic degradation. Understanding these mechanisms will assist researchers in developing new therapeutic strategies while formulating AMP mouth rinses [1]. Thus, the number of STAMPs targeting *S. mutans* were researched for selecting inhibition of pioneer caries bacteria [36]. C16G2 is a STAMP designed with antimicrobial specificity for *S. mutans* [37]. C16G2 utilizes *S. mutans* produced pheromone (competence stimulating peptide) which acts as the STAMP targeting domain against the cell surface of *S. mutans* [28]. The term C16G2, denotes the 16 amino-acid (C16) sequence of TFFRLFNRSFQTALGK molecule [38]. Whereas, the killing domain is designated as G2, which is derived from a broad spectrum antimicrobial peptide. These 2 peptide sequences are conjoined by a sequence of 3 glycine residues [37]. As per sequence analysis, C16G2 is an amphipathic and cationic alpha-helical peptide which is comparable with the conventional AMPs [39].

The hydrophobic property of C16G2 is substantially greater than that of individual moieties because of the stacking of hydrophobic residues [40]. CSPC16-*S. mutans* is a species-specific AMP but is separate from the ComD surface receptor [28]. A natural *S. mutans*-specific targeting sequence in this pheromone may become attached to a different receptor (lipids, exopolysaccharides, teichoic acid) on the bacterial surface before interaction with ComD. According to recent studies, C16G2 exerts bactericidal action by a mechanism involving interference with the cytoplasmic membrane. C16G2 build-up on *S. mutans* cell surface results in loss of membrane potential followed by efflux of intracellular contents and disruption of membrane integrity finally causing cell death. The mutual amphipathic characteristic of C16G2 and AMPs gives rise to the STAMP acting as a membrane damaging peptide but with higher target specificity [40]. It has been proposed that C16G2 specifically eradicates *S. mutans* from multispecies biofilms without impacting closely associated non-cariogenic oral streptococci in saliva-derived and planktonic biofilm systems [28,41].

Studies on C16G2 and oral biofilm:

An in-vitro study on human saliva-derived polymicrobial biofilms treatment with C16G2 showed reduction of *S. mutans* counts and revealed a benign oral microbial community with enhanced health-related bacteria populations and less detrimental gram-negative bacteria [42]. C16G2 is considered to be fast-acting against bacteria in under one minute of exposure. The advantage of rapid action in a shorter duration is adequate to us as oral hygiene rinses. C16G2 is soluble in aqueous solutions indicating that STAMP is easily amenable for use in the oral cavity through a mouth rinse medium [28,36,40,43]. Another in-vivo study evaluated efficacy of mouth rinse with C16G2 formulation showed reduction of both plaque and salivary *S. mutans* counts. The study findings also showed prevention of *S. mutans* regrowth despite frequent exposure to sugar.

This is because of reduction in lactic acid

production resulting in the elevation of pH which favors growth of healthy bacteria, thus rendering an unsuitable environment for growth of cariogenic bacteria. Thus, it might be feasible to develop a healthy non-cariogenic microbial ecosystem in the mouth through C16G2-mediated STAMP intervention in clinical practice [41]. An unimpaired dental biofilm without *S. mutans* resists later growth of exogenous *S. mutans* due to reduced sucrose intake of other microbes in the biofilm which delay cariogenesis. Thus the oral microbial community maintained by C16G2 treatment exhibit a healthy microbial population with non-cariogenic species such as *S. mitis*, *S. sanguinis* as well as reduced periodontitis associated gram-negative species *Fusobacteria* [42]. C16G2 was recognized by the US food and drug administration as an investigational drug for prevention of dental caries and has efficiently concluded phase 2 clinical trials [8].

CONCLUSION

C16G2 is an effective STAMP against dental caries that can be prepared in an aqueous formulation for use as an oral hygiene rinse. Its selective activity against *S. mutans* is helpful in caries preventive management. Development of C16G2 is a very significant advancement in oral biofilm management and caries prevention. Randomized clinical trials are required to evaluate the clinical utility of C16G2 and its effectiveness as a routine self-care practice.

ABSTRACT

Background: During the coronavirus disease 2019 (COVID-19) pandemic, adherence to suggested precautionary measures has been emphasized as important in preventing and curtailing its spread. However, strict adherence to precautionary measures can be demanding.

Methods: This cluster randomised controlled trial done among 1517 undergraduate dental students tested the effectiveness of 'dissonance induction' (DI) and 'assessment reactivity' (AR) in improving adherence to World Health Organization (WHO) measures as compared to a control group. At baseline, participants in the DI group were tested for their knowledge of precautionary measures, immediately followed by assessment of their adherence to them. This methodology was adapted to systematically reveal the poor adherence of the participants in their self-held cognitions, should there be any. The magnitude of dissonance was measured as the proportion of such dissonant cognitions held by an individual. In the AR group, at baseline, participants were asked about their attitudes alone toward measures. The control group was neither assessed for knowledge and adherence nor for attitudes toward the measures at baseline. Two weeks after the administration of these interventions in the DI and AR groups, the 3 study groups were assessed for adherence.

Results: The follow-up adherence scores in the DI group were found to be significantly higher (15.11 ± 4.1) compared to the AR (13.13 ± 2.01) and control (12.87 ± 2.97) groups as analysed by Kruskal-Wallis analysis of variance ($H = 243.5$; $P < .001$). Wilcoxon signed-rank test showed that the adherence scores significantly improved in the DI group from baseline to follow-up ($z = -8.84$; $P < .001$). Magnitude of dissonance at baseline was found to be a significant predictor of follow-up adherence scores ($R^2 = 0.255$).

Conclusion: This study found that DI is an easy intervention to bring an immediate and significant change in adherence to precautionary measures.

Introduction

The fact that coronavirus disease 2019 (COVID-19) was declared a public health emergency of international concern reflects the magnitude of the global crisis caused by this viral pandemic.¹ Since severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2), the virus that causes COVID-19, is a

novel virus with recent emergence among humans, humans are completely immune-naïve and consequently vulnerable to infection.² International experiences suggest that the transmission of the disease can be rapid in rather short periods of time.^{3,4} Though COVID-19 is associated with mortality, the case fatality rate was reported to be lesser for COVID-19 (2%) compared with severe acute respiratory syndrome (SARS) (10%) and Middle East Respiratory Syndrome (MERS; 34%). However, it was reported that COVID-19 has been responsible for more deaths than SARS and MERS combined. These findings reflect the more contagious, though less severe, nature of COVID-19 compared with SARS and MERS.⁵ It is for this reason that the greatest challenge ahead for health care systems is to curtail the rapidity and magnitude of transmission. As on 24 December 2020, official reports from the Ministry of Health and Family Welfare, Government of India suggest that 10.1 million individuals have been confirmed positive among suspected cases and contacts of known cases.⁶ These numbers illustrate the nature of transmission of the disease. Responsibility has been placed on the citizens of the nation to prevent themselves from getting affected. The World Health Organization (WHO) suggested precautionary measures of frequent hand washing, social distancing, avoiding touching face, nose, or mouth, practising respiratory hygiene, maintaining 1-meter distance from those coughing and sneezing, and refraining from smoking and activities that weaken the lungs. These measures have been widely circulated in various media platforms for people to assimilate and adopt.⁷ However, literature suggests that though persuasive health messages are often successful in bringing attitudinal changes among people, these changes are short-lived. More importantly, it has been strongly established by social psychologists that positive attitudes do not necessarily translate to positive behaviours. Therefore, more thorough and scientifically informed behavioural interventions are warranted to improve adherence to precautionary measures and combat the outbreak of this and other infectious diseases.

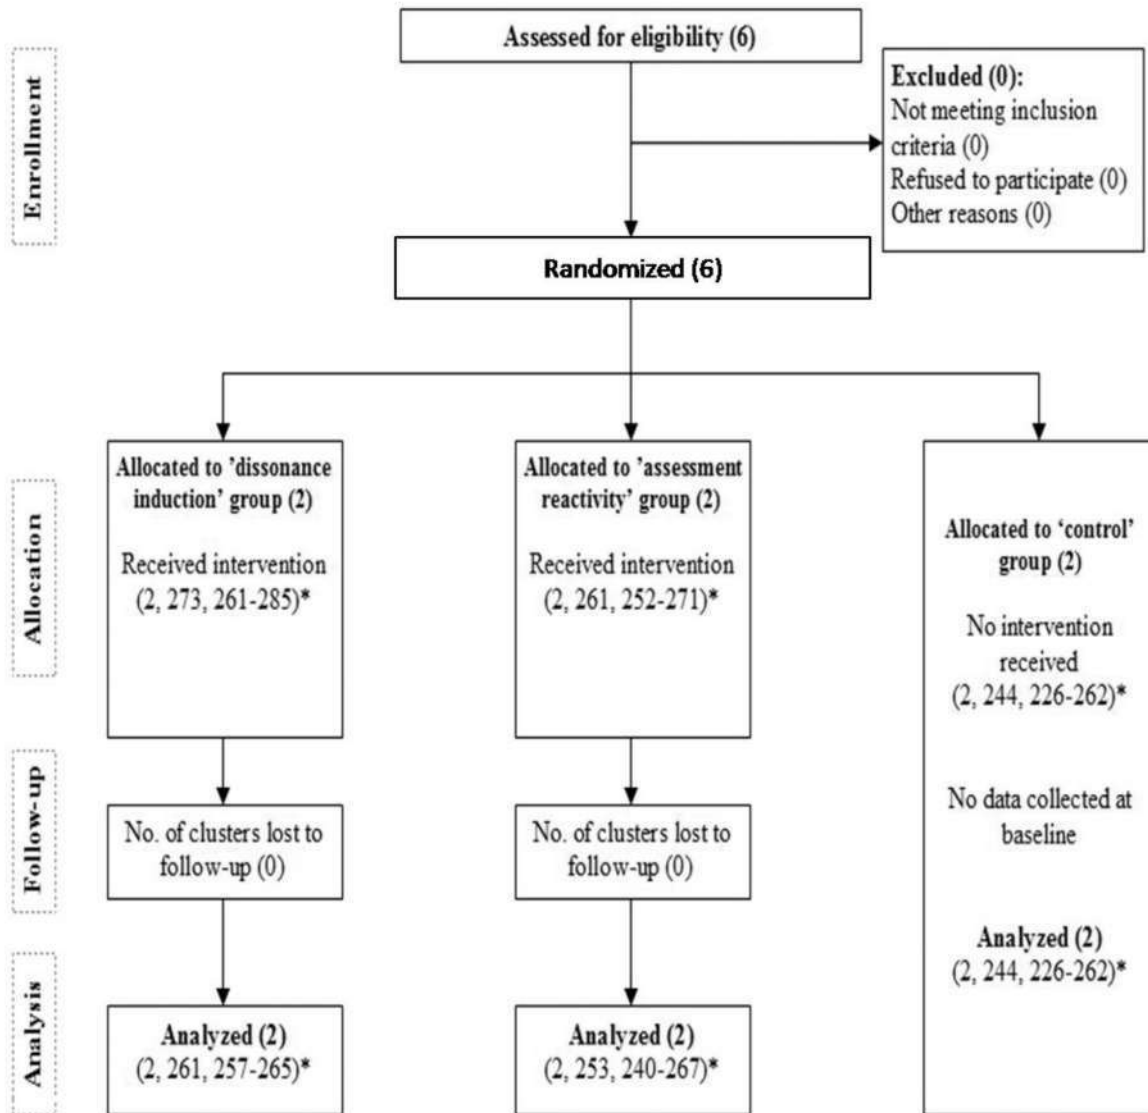

The benefits of answering questions, termed as 'question benefit effect' (QBE), about a behaviour in producing positive changes, though minor in magnitude, in that behaviour have been previously studied.⁸ Various theories have been proposed to explain the behaviour change following responding to questions on that behaviour. Sherman⁹ postulated that mental stimulation takes place while responding to questions about a behaviour that results in formation of cognitive representations or behavioural scripts. These cognitive representations get reactivated while the subject performs that behaviour and assists a positive behavioural change. Another explanation is the theory of attitude accessibility that proposes that the questions about behavioural intentions of individuals activate the attitudes intrinsic for that behaviour, making them more accessible in memory.¹⁰ This theory was tested with regard to healthy eating behaviours.¹¹ Cognitive dissonance is another explanation for QBE, which attempts to attribute the benefit to the cognitive conflict felt by reporting behaviours inconsistent with their beliefs. Cognitive dissonance, as proposed by Leon Festinger,¹² is an unpleasant drive state similar to hunger or thirst experienced when 2 psychologically inconsistent cognitions are simultaneously held by a person that is against the inner drive to maintain

harmony between one's attitudes/beliefs and behaviour. Aronson¹³ proposed that dissonance theory makes its clearest predictions when the people's self-concepts are violated by their own actions. Aronson also argued that passing on information to individuals in a persuasive manner would only result in attitudinal changes that are temporary. Dissonance-induced persuasion is more effective in bringing a behavioural change because individuals' inconsistent behaviour with their own self-concept creates a necessity to attain consistency between their self-concepts and behaviour. Assessment reactivity, on the other hand, is the influence of behavioural assessment at the present time on later behaviour. It was proposed that mere questioning about a behaviour influences an individual to change the behaviour in question.¹⁴ In the present study, the group where inconsistency of the subjects' behaviour with their own concepts is explicitly made evident to them by testing their knowledge and behaviour at baseline is identified henceforth as the 'Dissonance Induction' (DI) group. The group where mere questioning of attitudes was done at baseline is identified as the 'Assessment Reactivity' (AR) group. There is a control group which was neither tested for knowledge, behaviour nor for the attitudes at baseline. Our hypothesis (H1) was inducing dissonance among subjects by systematically making evident to them the poor adherence to their own cognitions results in better follow-up adherence to the precautionary measures. If the null hypothesis (H0) were to be true, there would be no difference in the follow-up adherence scores between the 3 study groups.

Methods

This cluster randomised controlled trial was conducted during the months of February and March 2020 following ethical approval from the Institutional Ethical Committee of SIBAR Institute of Dental Sciences (Pr.69/IEC/SIBAR/2020). The allocation ratio was 1:1:1 in the DI, AR, and control groups. Six teaching dental institutions (clusters) of the 16 functioning dental institutions in the southern Indian state of Andhra Pradesh were selected and 2 each were allocated to DI, AR, and the control groups after randomisation. The study details are depicted in Figure 1. All the study participants were provided with the necessary information on the purpose and process of the study without revealing the specific focus and objectives of the study. Consent was obtained prior to the subjects' participation in the study, and participation in the study was voluntary. Care was taken to ensure anonymity in the questionnaire, leaving no place for coercion. Since all the participants within a cluster received either the same intervention or no intervention, contamination between the study groups was not possible. Furthermore, study participants from each individual dental institution were neither aware of the alternative interventions tested in the study nor did they know about the parallel conduct of the study among students from other dental institutions.

DI at baseline: In the DI group, dissonance was induced at baseline by administering a self-administered, structured questionnaire that revealed the existing cognitive conflict, should there be any. This questionnaire consisted of 2

*(number of clusters, average cluster size, range of cluster size)

Fig. 1 – CONSORT flow diagram of the cluster randomized trial.

CONSORT = Consolidated Standard of Reporting Trials.

*Number of clusters, average cluster size, and range of cluster size.

sections: knowledge about COVID-19 precautionary measures and adherence to precautionary measures. To assess knowledge on COVID-19 precautionary measures, a combination of 6 WHO suggested precautionary measures and 6 distractor options was given for the participants to choose from. The adherence was assessed immediately after the participants had responded to the knowledge questions. This questionnaire served 2 purposes: making the subjects explicitly mention their self-concepts in the 'knowledge' section and making it evident for the subjects how consistent/inconsistent their actions were with their own cognition in the

'adherence section'. Dissonance was considered to be induced if a subject chose a WHO suggested precautionary measure in the knowledge section and reported his or her current adherence to that precautionary measure to be 'occasional' or 'never' as the poor adherence of the subjects with their self-held cognitions was systematically revealed to them. On the other hand, consonant cognitions refer to WHO suggested precautionary measures chosen by the subjects in the knowledge section for which they report their adherence to be 'often' or 'almost always'. The knowledge score (ks) of a subject 'i' was calculated using the formula $ks(i) = N - Z$, as

suggested by Kurz, where N is the number of correct responses chosen by that subject and Z refers to the number of incorrect responses.¹⁵ This ensures that a subject who chooses all the responses randomly will get a 'zero' knowledge score. The baseline adherence to WHO suggested COVID-19 precautionary measures was assessed on a 4-point Likert scale (0-3) with higher score indicative of better adherence. The magnitude of dissonance (M_D) was calculated as the number of dissonant cognitions divided by the sum of number of consonant and dissonant cognitions ($M_D = N_{dc} / (N_{cc} + N_{dc})$; where N_{cc} refers to number of consonant cognitions and N_{dc} refers to number of dissonant cognitions).

Baseline attitudinal measurement in the AR group: In the AR group, a self-administered questionnaire inquiring the attitudes of the subjects toward WHO suggested COVID-19 precautionary measures was administered. In contrast with the DI group, these participants were neither assessed on their knowledge of the precautionary measures nor were they asked about their adherence to precautionary measures at baseline. The attitudes were documented on a 4-point Likert scale (0-3) with higher scores indicative of more positive attitudes.

The control group was not assessed for either the knowledge and practice or the attitudes toward precautionary measures at baseline.

Assessment of adherence in the study groups at follow-up: During the follow-up, 2 weeks after the administration of corresponding questionnaires in the DI and AR groups, self-reported adherence to the WHO suggested COVID-19 precautionary measures was documented in all the 3 study groups on a 4-point Likert scale (0-3) with '0' indicating nonadherence and '3' indicating perfect adherence. Adherence score of a subject at the follow-up was calculated as the sum of scores obtained for the responses to the 6 precautions of interest. Therefore, the follow-up adherence scores range from 0 to 18, with '0' indicating nonadherence to all the 6 precautionary measures and '18' indicating perfect adherence to all the precautionary measures. A total of 60 students were lost to follow-up across both the intervention groups and were excluded from the analysis. The final sample included 1517 subjects with 522 in the DI group, 507 in the AR group, and 488 in the control group.

Statistical Analysis: SPSS version 2.0 software was used for descriptive statistics and data analysis. The Wilcoxon signed rank test identified the change in adherence scores from baseline to follow-up in the DI group, Spearman's correlation test evaluated the correlation between attitudinal scores at baseline and follow-up adherence scores in the AR group, Kruskal-Wallis analysis of variance tested the differences in follow-up adherence scores between the study groups, and simple linear regression analysis was used for the DI group with follow-up adherence score as the dependent variable and magnitude of dissonance as the explanatory variable.

Results

The response rate was 68.4% in the DI group, 66% in the AR group, and 63.2% in the control group. There was no significant difference in the gender distribution between the study

Table 1 – Distribution of responses to the knowledge test on COVID-19 precautionary measures in the Dissonance Induction group at baseline (n = 522).

Precautionary measure	Response	n (%)
Use prophylactic antibiotics	Yes	47 (9)
	No	475 (91)
Eat plenty of garlic	Yes	112 (21.45)
	No	410 (78.55)
Avoid touching your face	Yes	425 (81.41)
	No	97 (18.59)
Refrain from smoking and other activities that weaken the lungs	Yes	259 (49.61)
	No	263 (50.39)
Use hand dryers after washing your hands	Yes	97 (18.58)
	No	425 (81.42)
Cover your mouth and nose when coughing or sneezing	Yes	499 (95.6)
	No	23 (4.4)
Maintain at least 1 meter distance between you and people sneezing or coughing	Yes	495 (94.82)
	No	27 (5.18)
Take regular hot water baths	Yes	73 (13.98)
	No	449 (86.02)
Practice social distancing and avoid unnecessary travel	Yes	485 (92.91)
	No	37 (7.09)
Stay in hot and humid climates	Yes	51 (9.77)
	No	471 (90.23)
Stay away from mosquitoes as they can transmit SARS-CoV-2	Yes	45 (8.62)
	No	477 (91.38)
Wash your hands frequently with alcohol-based hand rub	Yes	510 (97.7)
	No	12 (2.3)

COVID-19 = coronavirus disease 2019; SARS-COV-2 = severe acute respiratory syndrome-coronavirus 2.

groups with female students representing 80.07% (418) of the DI group, 77.51% (393) of the AR group, and 78.07% (381) of the control group.

Baseline observations in the DI group: Table 1 shows the participants' responses to knowledge questions in the DI group at baseline. The mean knowledge score of COVID-19 precautionary measures among the participants from the DI group was 3.23 ± 2.15 (95% CI 3.04-3.41), after adjusting for the incorrect responses. The mean score for magnitude of dissonance was observed to be 0.26 ± 0.18 , which suggests that the proportion of dissonant cognitions on an average was slightly more than 25%. The mean adherence to precautionary measures score in the DI group at baseline was 13.02 ± 3.74 (95% CI 12.69-13.34).

Baseline observations in the AR group: The mean attitudinal score toward COVID-19 precautionary measures in the AR group at baseline was 14.02 ± 3.6 , where a score of 18 was indicative that the subject is most likely to practice all 6 precautionary measures suggested.

Follow-up observations in the study groups: An apparent difference was noted among the 3 study groups with regard to their mean follow-up adherence scores in practicing the COVID-19 precautionary measures, with the DI group demonstrating higher scores compared to AR and control groups (Figure 2). Significantly higher adherence scores in DI group were suggestive of the more thorough adherence to precautionary measures in the DI group compared to AR and control groups at follow-up. No significant differences were noted between the AR and control groups in post hoc tests for

Fig. 2 – Box plot showing differences in the follow-up adherence scores between the study groups.

Table 2 – Differences in follow-up adherence scores to COVID-19 precautionary measures between the study groups.

Group	N	mean ± SD	95% CI	Mean rank	H (df, N)	P value	P value (post hoc tests)		
							DI - AR	DI - C	AR - C

Discussion

DI was found to be an effective way to bring positive changes in adherence to COVID-19 precautionary measures, demonstrating significant positive differences with the AR and control groups, and consequently, the null hypothesis (H_0) can be rejected in support of H_1 . This study attempted to make subjects in the DI group experience the cognitive conflict at baseline by testing their knowledge on and immediately inquiring about their practice of COVID-19 precautionary measures. Such inquiry results in induction of dissonance, a state of cognitive conflict, by making the discrepancy between cognition and behaviour explicitly evident to the respondent. This may influence people to adopt behaviours that they believe are health-promoting in nature. Aronson et al¹⁶ referred to this method as creation of dissonance by hypocrisy induction. Aronson et al¹⁶ successfully tested the effectiveness of this method in overcoming denial and improving the intentions to use condoms, where hypocrisy was induced by having the subjects publicly advocate condom use and then systematically making the subjects aware of their own previous failures in condom use. Dickerson et al¹⁷ reported behaviours conducive to water conservation among the hypocrisy-induced group. Aronson argued that the change in people's attitudes through informational campaigns is short-lived because such a change is brought about by an external source. They proposed that little investment of the self in formation of the attitude is the reason behind the impermanent nature of these changes and such attitudes are vulnerable for change if there is a stronger counterargument by a different external source in the future. Aronson et al¹⁸ suggested that dissonance-generated persuasion is effective in resulting a long-term change as there is the opportunity for critical reflection and investment of the self in the process of attitudinal or behavioural change. In the present study, magnitude of dissonance explained more than a quarter of the variance in the follow-up adherence scores in the DI group adding strength to the argument that induction of dissonance is effective in bringing positive health behavioural changes. Wilding et al¹⁹ reported that the dissonance-enhanced QBE condition was more effective in health behavioural modification compared to a standard QBE intervention. Dissonance was also discussed as the most plausible mechanism explaining QBE in the meta-analyses conducted by Wood et al¹¹ and Spangenberg et al.²⁰

Besides induction of dissonance, another intervention tested in this study was mere questioning about the attitudes toward COVID-19 precautionary measures at baseline without assessing the knowledge and practice of these measures. The existing evidence regarding whether mere questioning of the attitudes relating to a behaviour may bring a positive behavioural change is equivocal.^{14,18,21} In the present study there was no significant difference between the AR and control groups in the follow-up adherence scores. Moreover, the attitudes toward practice of the precautionary measures at baseline in the AR group demonstrated no correlation with the follow-up adherence scores. Spangenberg et al²² also reported no differences between participants who were asked and not asked to predict their behaviour. These findings, however, were inconsistent with those reported by Wood

et al,¹¹ in which participants who were asked to report their intentions demonstrated more accessible attitudes compared to those who were not. Ayres et al²³ proposed that QBE alone is insufficient in promoting health behaviours; a combination of motivation and QBE was reported to be effective in significantly increasing behaviour in a randomised controlled trial. Thus, the present study adds strength to the existing QBE research and postulates DI, over mere questioning about attitudes, as an efficient intervention to promote healthy behaviours with regard to COVID-19 precautionary measures.

Possessing concrete insight into positive health behaviours does not mean practice of these behaviours.²⁴ Also, it was reported in the literature that people believe their behaviour to be better than their actual behaviour.²⁵ Therefore, one of the fundamental goals of health behavioural research is to close the gap between knowledge and behaviours. As a cost-effective alternative to close this gap, QBE was previously tested in different domains of health care such as health screening,²⁶ health check-ups,²⁷ vaccination,²⁸ adoption of health-promoting behaviours, and reduction of risk behaviours.¹⁹ However, this is the first time, to our knowledge, that QBE has been tested for behavioural change with respect to limiting the spread of an infectious disease where strict adherence to suggested precautionary measures is regarded as the best way to combat the spread. It is evident from this study that though the study population possesses good knowledge of the COVID-19 precautionary measures to be followed; they also held some misconceptions among which eating plenty of garlic was the most common. Other common misconceptions identified were the need to take regular hot water baths; the need to use hand dryers after hand wash; and the need to stay in hot and humid climates. Refraining from smoking was identified by only less than half of the participants in the intervention group as a precautionary measure. The problem with holding erroneous beliefs is that the unwarranted practice of these beliefs may act as a compensatory mechanism for people to ignore the actual precautionary measures to be followed. For instance, a person from India who holds a notion that staying in hot and humid climates is protective against severe acute respiratory syndrome-coronavirus 2 may not feel the necessity to practice social distancing. This study highlights some of the erroneous notions held by the dental students and provides an indication of the necessity to more effectively communicate the precautionary measures to reduce the transmission of COVID-19.

The limitations of this study are randomisation at the level of the dental institution; short follow-up time; increased accessibility to information related to COVID-19 through the study period. Randomisation was not done at the participant level to prevent contamination bias.²⁹ Students from the same institution randomised to any of the 3 study groups may share their experiences with colleagues in a different study group than theirs; this is the reason why cluster randomisation was preferred. However, cluster randomisation carries the risk of reduced statistical power. A follow-up time of only 2 weeks was considered in the present study. It was reported in the literature that QBE decays with time. However, in the context of epidemics, even short-term changes in behaviours toward the positive are of tremendous importance. In the literature, follow-up times after administering

the questionnaire varied over a wide range in the previous QBE research with Van Kerckhove et al³⁰ measuring the dependent variable immediately after questioning and Murray et al³¹ reported a time interval of 5 years between administration of questionnaire and measurement of the outcomes. It is important to point here that all study participants, regardless of the study groups, had increased accessibility to COVID-19 information through the study period, which may have an influence on their adherence to the precautionary measures. Nevertheless, access to information is common for participants in all study groups and any possible influence could have affected the follow-up adherence scores in all groups. Another limitation in this study is the gender imbalance with 78.5% of the study participants being females. However, this imbalance is consistent with the existing gender-based imbalance in enrolment into dentistry in India.³² DI was found to be a low-cost, rapid, and effective intervention in this study to improve adherence to COVID-19 precautionary measures. We propose that a more definitive argument in favour of making use of DI as a cost-effective method can be made by comparing the adherence levels to healthy behaviours between DI and strict auditing. Such establishment of DI as a cost-effective alternative goes a long way in the determination of the choice of interventions for behaviour change and not just with regard to COVID-19 but also in the broader context of various health behaviours. Future research on QBE in health behavioural research must also attempt randomisation at an individual level and optimum follow-up times.

Abstract: Healthcare workers (HCWs) in India received the AZD1222 and BBV152 vaccines from January 2021 onwards. The objective of this study was to compare the immune response (seropositivity rate and geometric mean titer (GMT), and 95% confidence interval (CI)] against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in HCWs who received these vaccines, after the first and second doses. Therefore, the total immunoglobulin (Ig) levels specific to SARS-CoV-2 were measured using quantitative enzyme-linked immunosorbent assay (ELISA). The study population of 133 HCWs consisted of two groups in which the immune response was measured for the AZD1222 and BBV152 vaccines. Data collection was performed from 6 February to 20 August 2021. Four weeks after the first and second dose, the odds ratio of seroconversion for AZD1222 and BBV152 vaccine was 10.3 times (95% CI: 4.5–23.7) and 15.9 times (95% CI: 6.3–39.9), respectively. The GMT was 6392.93 and 6398.82 U/mL for AZD1222 and 1480.47 and 990.38 U/mL for BBV152 after the first and second doses, respectively. Both vaccines elicited an immune response, but the seroconversion rate and GMT after each dose were significantly higher for AZD1222 than those for the BBV152 vaccine in this study.

1. Introduction

COVID-19 infection is a severe acute respiratory syndrome caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) [1]. SARS-CoV-2 is a newly emergent coronavirus, first recognized in Wuhan, Hubei province, China, in December 2019. This is a positive-sense, single-stranded, highly contagious RNA virus that can be transmitted among humans. According to an announcement made by the Health Ministry of India, the COVID-19 vaccination drive started with two vaccines: AZD1222 and Bharat Biotech BBV152 vaccines, in January 2021. The two vaccine products were the non-replicating chimpanzee adenovirus vaccine vector (ChAdOx1) from the Serum Institute of India (SII), Pune, India (in collaboration with the University of Oxford, U.K., and pharma giant, AstraZeneca) and an inactivated virus vaccine from the Bharat Biotech Ltd., Hyderabad, India (in collaboration with the National Institute of Virology of Indian Council of Medical Research (ICMR), India). Priority for vaccination was given to an estimated thirty million healthcare and frontline workers [2]. Experts in disease control, immunization, public health, and information technology recommended strategies to be employed in India's COVID-19 vaccination program. According to the strategy for COVID-19 vaccination in India, the country with the second-highest population and cases of infected patients, two

Dr. L. KRISHNA PRASAD

SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

vaccines, AZD1222 and BBV152, were approved by the Drugs Controller General of India (DCGI), based on results from clinical trials [3].

In India, the first round of vaccination was administered to current healthcare workers, and the second round to priority groups, such as the elderly population, people with comorbidities, pregnant women, and children. Vaccination of people older than 60 years and those older than 45 years with comorbidities began on 1 March 2021 [4].

In an earlier study, researchers evaluated the diagnostic performance of seven rapid IgG/IgM tests and the EUROIMMUN IgA/IgG ELISA for antibodies against SARS-CoV-2 in patients with COVID-19. Their results demonstrated that commercial automated assays and ELISAs are suitable for the detection of IgG and total Ig antibodies against SARS-CoV-2 [5]. The present study mainly focused on evaluating post-vaccination immune responses in healthy individuals.

This study aimed to determine immune response and seroconversion after two doses of the recommended vaccines in a study group of healthcare workers by estimating the total immunoglobulin specific to the spike protein of SARS-CoV-2. Based on the literature on the methodology for the quantitative estimation of total immunoglobulin, we chose enzyme-linked immunosorbent assay (ELISA) to estimate the level of antibodies against the recombinant spike protein of SARS-CoV-2 [6–8].

2. Materials and Methods

2.1. Study Institutions

This study was conducted at the All India Institute of Medical Sciences Mangalagiri (AIIMS, M.G.), Andhra Pradesh, in collaboration with the SIBAR Institute of Dental Sciences, Guntur, Andhra Pradesh.

2.2. Study Design and Participants

This was a prospective cohort study.

2.3. Study Cohorts

For group 1, we recruited adult healthcare workers aged >18 years who received the AZD1222 vaccine at the COVID-19 vaccination center at AIIMS, M.G. The AstraZeneca AZD1222 vaccine was recommended by the government of India for patients aged \geq 18 years. As per the recommended schedule, 2 doses (0.5 mL each) of the vaccine were administered at an interval of 4 weeks to all study participants of one group [9]. The first dose of both vaccines was administered to the study groups of healthcare workers on January 18, 2021. The immune response to the vaccine was measured 4 weeks after administration of the first and second doses, and then 24 weeks after the second dose, to verify the rate of seroconversion. This study cohort consisted of 88 participants (N = 88).

For Group 2, we recruited adult healthcare workers aged >18 years who received the BBV152 vaccine at the COVID-19 vaccination center at the SIBAR Institute of Dental Sciences, Guntur, Andhra Pradesh. The BBV152 vaccine was developed in India by Bharat Biotech, in collaboration with the Indian Council of Medical Research (ICMR)—National Institute of Virology (NIV). This group received the second dose of the BBV152 vaccine 28 days after the first dose, as per the recommendations [9].

Seropositivity to the vaccine was measured at 4 weeks after administration of the first and second doses and 24 weeks after the second dose to verify the rate of seroconversion. This study cohort consisted of 45 participants (N = 45).

A total of 133 HCWs who, reportedly, did not have a previous COVID-19 infection—that is, who were SARS-CoV-2 naïve—were enrolled into the study. HCWs on steroids, severe comorbid illnesses, children, and pregnant women were excluded from the study.

Data collection for this study began 6 February 2021 and ended 20 August 2021.

2.4. Study Group for Cut-Off Value Determination for ELISA Testing

Twenty-five healthy volunteers who had never been exposed to or immunized against COVID-19 were also enrolled to confirm the optical density (450 nm) 0.02, with the standard high control (units/mL) of “0” stated in the test kit manufacturer’s instruction manual.

As per the Indian Council of Medical Research (ICMR)’s COVID-19 testing guidelines, twenty-five healthy patients were not tested, since they lacked COVID-19 symptoms, and 5 mL whole blood samples were collected from these patients to determine the cut-off value for the total SARS-CoV-2 spike antibody level.

2.5. Blood Samples and Biosafety

Strict infection control measures were taken during blood collection, and complete personal protective equipment (PPE) was worn by all personnel involved in the study during collection and processing of samples and testing in the biosafety level 2 (BSL2) laboratory [10].

Whole blood samples (5 mL) were collected in plain vacutainer rapid serum tubes from each participant 4 weeks after the first dose of vaccination. During the follow-up period, a second blood sample was collected 4 weeks after the second dose of vaccination and again at 24 weeks after the second dose.

The serum was separated from whole blood immediately after collection and stored in separate aliquots at $-20\text{ }^{\circ}\text{C}$ in a deep freezer until further testing was performed in batches.

2.6. Antibody Measurement by Ig Total ELISA

The Human SARS-CoV-2 Spike (trimer) Ig Total ELISA Kit (Invitrogen-BMS2323, ThermoFisher Scientific Inc., Vienna, Austria) was used to detect the total Ig level in serum samples. The test was a solid-phase sandwich ELISA, which was designed to detect and quantify the level of total Ig against human SARS-CoV-2 in the serum.

Trimerized spike protein was pre-coated in the wells of the supplied microplate. Samples and controls, including a high control, were used as a standard; these were then added to these wells and bound to the immobilized (capture) spike protein. The wells were washed, and secondary Ig antibodies conjugated to horseradish peroxidase (HRP) were added and bound to the primary antibodies. The wells were washed, and a substrate solution was added to react with the enzyme complex to produce a measurable signal. The total Ig antibody assay recognizes IgG, IgM, and IgA. The intensity of this signal is directly proportional to the concentration of the antibodies present in the original specimen.

Each ELISA run was performed with standards and controls in duplicates. The absorbance was measured using a BioTek Epoch2 microplate reader (BioTek Instruments, Inc., Winooski, VT, USA). Standard curves were plotted using four parametric log–log curves fitted via Gen5™ v3.11 Microplate Reader and Imager Software (BioTek Instruments, Inc., Winooski, VT, USA). The background absorbance was subtracted from all data points, including the standards, unknown serum samples, and controls, prior to plotting. The concentrations of unknown serum samples and controls were determined using the standard curve (four parameter logistic (4PL) regression). We read the absorbance at 450 nm and determined the results of the assay quantitatively, as per the kit instructions over the range of 0 to 4000 units/mL total human SARS-CoV-2 Ig.

To set the cut-off value for results analysis, we have used change-point analyses [11]. Therefore, the cut-off antibody level was determined using the following formula:

$$\text{Cut-off} = \text{Mean} + 3 \text{ times the standard deviation}$$

Based on the above calculation, a total SARS-CoV-2 spike antibody titer greater than the cut-off value of 907.58 U/mL was considered seropositive and confirmed seroconversion.

An additional third sample was collected from participants in both groups who did not demonstrate any detectable level of total spike antibody or whose antibody level was below the calculated cut-off value in the samples collected 4 weeks after the second dose.

2.7. Statistical Analysis

The data were entered into a Microsoft Excel (MS Excel) spreadsheet and were analyzed using Epi-Info, IBM SPSS, and Open Epi software. The primary outcome of interest was seroconversion. The immune response to the vaccine—that is, seropositivity—was treated as a nominal variable with the following categories: seroconverted (yes) and seroconverted (no) with antibody titers more than 907.58 U/mL and less than 907.58 U/mL, respectively. The key variables of interest were the immune response to each vaccine, AZD1222 and BBV152, 4 weeks after the first and the second dose and 24 weeks after the second dose, in individuals who did not have prior history of COVID-19.

The chi-square test and Fisher's exact test were used to test the statistical significance of the association between two categorical variables. In this cohort study, the odds ratio (OR) and relative risk (RR) with corresponding 95% confidence intervals (CI) were calculated.

The geometric mean titer (GMT) and standard deviation (SD) with 95% CI were calculated for the antibody titers four weeks after the first and second doses of AZD1222 and BBV152 vaccines. An independent sample t-test was applied to determine whether there was any significant difference in GMTs of AZD1222 and BBV152 vaccines four weeks after the first and second doses.

A difference was considered statistically significant if the *p*-value was less than or equal to 0.05.

3. Results

Table 1 presents the demographic characteristics of the study participants. The AZD1222 vaccination group consisted of 57.9% (51/88) males and 42.1% (37/88) females. In the BBV152 vaccination group, 46.7% (21/45) of the participants were males and 53.3% (24/45) were females. The age range was 18–56 years (median 34 years) in the AZD1222 group and 19–52 years (median 26 years) in the BBV152 group. The mean age of participants was 33.1 and 29.8 years for the receivers of the AZD1222 and BBV152 vaccines, respectively.

Table 1. Demographic data of the participants in this study.

Participants	Characteristics	Vaccine	
		AZD1222 N = 88	BBV152 N = 45
Age, years	Range	18.00–56.00	19.00–52.00
	Mean age (SD)	33.1 (6.7)	29.8 (9.4)
	Median age (IQR)	34 (29.00–37.00)	26 (22–36)
Age, years	<20 (N, %)	2 (2.3)	1 (2.2)
	20–29	22 (25)	25 (55.6)
	30–39	53 (60.2)	11 (24.4)
	>40 (N, %)	11 (12.5)	8 (17.8)
Gender	Male (N, %)	51 (57.9)	21 (46.7)
	Female (N, %)	37 (42.1)	24 (53.3)

Abbreviations: SD: standard deviation; IQR: interquartile range.

As seen in Table 2, 71 out of 88 individuals (80.7%) had seroconversion from the AZD1222 vaccine 4 weeks after the first dose, whereas only 13 out of 45 individuals (28.9%) had seroconversion from the BBV152 vaccine 4 weeks after the first dose, and the difference was found to be highly statistically significant. Four weeks after the first dose, the seroconversion from the AZD1222 vaccine was 10.3 times (95% CI for odds ratio: 4.46–23.67) greater than that from BBV152. Meanwhile, 79 out of 88 individuals (89.8%) had seroconversion from the AZD1222 vaccine 4 weeks after the second dose, whereas only

16 out of 45 individuals (35.6%) had seroconversion from BBV152 vaccine 4 weeks after the second dose, and the difference was highly statistically significant. Four weeks after administration of the second dose, the seroconversion from the AZD1222 vaccine was 15.9 times (95% CI for odds ratio: 6.33–39.96) greater than that from BBV152 vaccine.

Table 2. Comparison of seroconversion rate 4 weeks after the first dose and the second dose of AZD1222 and BBV152 vaccines in SARS-CoV-2 naïve participants (N = 133).

Characteristics	SARS-CoV-2 Naïve Participant #		Odds Ratio, [95% CI], <i>p</i> Value	Relative Risk [95% CI]
	AZD1222 Vaccine	BBV152 Vaccine		
4 weeks after the first dose Seropositivity rate (%)	71/88, (80.7)	13/45, (28.9)	10.28 [4.46, 23.67] * <i>p</i> < 0.0001	2.79 [1.75, 4.47]
4 weeks after the second dose Seropositivity rate (%)	79/88, (89.8)	16/45, (35.6)	15.91 [6.33, 39.96] * <i>p</i> < 0.0001	2.53 [1.69, 3.77]

May include asymptomatic COVID-19 participants. * 95% CI for odds ratio calculated by the Wald method using WINPEPI software.

As shown in Table 3, the GMT (and SD) of the antibody titer (U/mL) measured 4 weeks after the first dose of AZD1222 and BBV152 vaccines were 6392.93 (4.92) and 1480.47 (9.32), respectively. An independent samples *t*-test was applied, and the difference was found to be highly statistically significant. The GMT (and SD) of the antibody titer (U/mL) measured 4 weeks after the second dose of AZD1222 and BBV152 vaccines were 6398.82 (3.24) and 990.38 (5.26), respectively. An independent samples *t*-test was applied, and this difference was found to be highly statistically significant.

Table 3. Geometric mean (and SD) antibody titer after the first and second dose of AZD1222 and BBV152 vaccines in SARS-CoV-2 naïve participants.

Characteristics	SARS-CoV-2 Naïve Participant #		<i>p</i> Value
	AZD1222 Vaccine, N = 84	BBV152 Vaccine, N = 17 (Four Weeks after First Dose) N = 25 (Four Weeks after Second Dose)	
	Antibody Titer, Geometric Mean (SD) [95% CI], in U/mL	Antibody Titer, Geometric Mean (SD) [95% CI], in U/mL	
4 weeks after the first dose	6392.93 (4.92) [6391.88–6393.98]	1480.47 (9.32) [1476.04–1484.9]	0.0001
4 weeks after the second dose	6398.82 (3.24) [6398.13–6399.51]	990.38 (5.26) [988.31–992.44]	0.0013

May include asymptomatic participants with COVID-19. Differences were considered statistically significant at *p*-value < 0.05.

Relative risk = 0.71, 95% CI for relative risk= (0.20, 2.49). As seen in Table 4, in total, 3 out of 19 individuals (15.8%) and 6 out of 27 individuals (22.2%) had seroconversion from the AZD1222 and BBV152 vaccine, respectively, 24 weeks after the second dose, but the difference was not statistically significant.

Table 4. Seroconversion from the AZD1222 and BBV152 vaccines 24 weeks after the second dose (N = 46) without previous COVID-19 infection.

Immune Response to Vaccine Twenty-Four Weeks after the Second Dose of Vaccine	Seroconverted	
	Yes	No
AZD1222	3 (15.8%)	16 (84.2%)
BBV152	6 (22.2%)	21 (77.8%)

Fisher exact test, $p = 0.88$. Odds ratio = 0.66, 95% CI for odds ratio by the Wald method = (0.14, 3.03).

4. Discussion

The World Health Organization (WHO) accelerated the development of COVID-19 vaccines worldwide at the beginning of 2020 in order to control the COVID-19 pandemic. Among several vaccine preparations, the recombinant coronavirus spike (S) protein, a replication-deficient simian adenoviral vaccine (ChAdOx1-S), and a BBV152 inactivated viral vaccine were recommended by WHO [12]. The present cohort study evaluated the immune response of healthcare workers against SARS-CoV-2 spike protein by estimating the total Ig titer after the administration of AZD1222 and BBV152 vaccines. We found that the seropositivity rate four weeks after the first dose was significantly higher in AZD1222 than in BBV152 vaccine recipients.

Furthermore, we also found that the seropositivity rate four weeks after the second dose was significantly higher in AZD1222 vaccine vs. BBV152 vaccine recipients. Our study findings are similar to those of Singh et al. (2021), who found that the seropositivity rate of antispikes antibody was significantly higher in Covishield (AZD1222 vaccine) vs. Covaxin (BBV152 vaccine) recipients (98.1 vs. 80.0%; $p < 0.001$) [13].

We also found that the geometric mean (and SD) of the antibody titer measured 4 weeks after the first and second doses of AZD1222 and BBV152 vaccines was significantly higher with the AZD1222 than with the BBV152 vaccine. A study by Singh et al. (2021) found that, after the administration of a second dose of Covaxin, the GMTs with 95% CI and median (IQR) antispikes antibody titer only increased significantly after two doses. In contrast, the Covishield vaccine showed a greater than threefold increase in the antispikes antibody GMT, even after a single dose.

However, the seropositivity rates 24 weeks after the second dose of AZD1222 and BBV152 vaccines did not show any statistically significant difference. Individuals who were infected with SARS-CoV-2 prior to receiving the AZD1222 and BBV152 vaccines did not report a significantly different seropositivity rate 4 weeks after the first and second doses of the AZD1222 and BBV152 vaccines.

A study revealed that, in the first phase (1/2) of a UK clinical trial testing two doses of the ChAdOx1 nCoV-19 (Covishield) vaccine, there was a significant increase in anti-spikes IgG antibody after 56 days compared to its median titer after 28 days [14]. Voysey et al. (2021) reported the clinical efficacy of the above vaccine in phase 2/3 of trials conducted in the UK and Brazil and found that this vaccine was effective against symptomatic COVID-19 [15,16]. Indeed, the numerous freely available basic research data on the mechanisms of SARS-CoV-2 infection have convinced most developers of innovative vaccines to focus their efforts on inducing an immune response against the spike protein. The S protein of SARS-CoV-2 is the most suitable antigen for inducing neutralizing antibodies against the pathogen [17]. In one such study, the researchers evaluated antispikes protein receptor-binding domain (S-RBD) antibodies, which represent a useful means of estimating the individual protection against SARS-CoV-2 infection, and observed a significant decrease in anti-RBD IgG levels within a short period following a complete two-dose vaccination cycle [18].

We have not estimated the antibody level in the study groups before vaccination, because the virus-specific neutralizing antibodies (NAbs), induced through either infection or vaccination, have the ability to block viral infection. The level of NAbs has been used as the gold standard to evaluate the efficacy of vaccines against smallpox, polio, and

influenza viruses [19]. The rationale behind measuring antibodies before vaccination is because previous infection is associated with a stronger immune response after vaccination [20].

Various studies have reported increasing levels of neutralizing antibodies of IgM and IgG to SARS-CoV-2 at different time intervals. Long et al. (2020) reported that, in 285 patients with COVID-19 infection, there were acute antibody responses to SARS-CoV-2 [21]. Within 19 days, one hundred percent of the patients were positive for Immunoglobulin G (IgG). The seroconversion of IgG and IgM occurred either simultaneously or sequentially. In addition, after symptom onset, the proportion of patients with virus-specific IgG positivity reached 100% at approximately 17–19 days. Virus-specific IgG and IgM antibody titers increased during the first 3 weeks after symptom onset.

There are many different vaccines prepared using different platforms, including recombinant vectors, DNA, mRNA in lipid nanoparticles, inactivated viruses, live attenuated viruses, and protein subunits against SARS-CoV-2 [22]. India had approved AZD1222/Covishield, a monovalent vaccine, and BBV152/COVAXIN, a whole virion-inactivated SARS-CoV-2 vaccine [23].

Based on immunogenicity studies in humans, the rate of seroconversion (a four-fold or greater increase over baseline) to S-binding antibodies was over 98% and 99%, 28 days after the first and second dose, respectively, in participants who were seronegative at baseline. The rate of seroconversion, as measured in a live neutralization assay, was over 80% and over 99%, 28 days after the first and the second dose, respectively, in participants who were seronegative at baseline [24].

The SARS-CoV-2 spike protein gene is expressed in the AZD1222 vaccine [25] and instructs the host cells to produce the S-antigen protein, which is unique to SARS-CoV-2. This allows the body to mount an immune response, and this information is retained in memory immune cells. The results of a clinical trial based on a median follow-up of 80 days showed that the efficacy of two doses of vaccine was 63.1%, irrespective of the interval between the doses. Efficacy tended to be higher when the interval was longer. The data reviewed at this time support the conclusion that the known and potential benefits of the AZD1222-S/nCoV-19 (recombinant) vaccine outweigh the risks [26].

The present study estimated antispikes immunoglobulin levels in vaccinated populations to evaluate the immune response to vaccines as a convenient tool for assessing immunological response. This has been supported by a study conducted by researchers on the long-term persistence of SARS-CoV-2 spike protein-specific and neutralizing antibodies in recovered COVID-19 patients. Their findings corroborate the reliability of estimating the antispikes immunoglobulin levels as a convenient tool for assessing the immunological response of COVID-19-infected individuals to quantify the immunogenicity of the vaccines and therapeutic effects [27].

Finally, massive vaccination campaigns are expected to elucidate several critical aspects of the SARS-CoV-2 immunity. As larger populations get vaccinated, the durability of the immunity induced by the different vaccine strategies, as well as the finer details of the immune responses elicited, will emerge, including in those individuals with suboptimal immunity [28].

The limitations of this study included the small number of participants due to the high cost of the test kit and insufficient funds to support the testing of a larger number of participants. The lack of baseline antispikes (S) serology is also a limitation of the study.

5. Conclusions

We found that the seropositivity response was significantly better in the AZD1222 group than in the BBV152 group, 4 weeks after the second vaccine dose, in 133 HCWs. Seropositivity response was also improved 24 weeks after the second dose in the BBV152 group compared to the AZD1222 group amongst 46 HCWs, but the difference was not statistically significant. This study found a low seroconversion rate in the study group vaccinated with the inactivated viral vaccine compared to the live vaccine.

Leukocyte Adhesion Deficiency-1 with Oral Manifestations – A Rare Case Report

Sethumanjusha Saranu, Yalamanchili Samata, Nunsavathu Purnachandra Rao Naik, Garikipati Anoop
Department of Oral Medicine and Radiology, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Leukocyte adhesion deficiency 1 (LAD) is a rare, inherited disorder portrayed by the inability of leukocytes to emigrate from the bloodstream toward sites of inflammation. LAD should be considered a rare but possible disorder in patients with persistent periodontal problems. This paper presents a case of leukocyte adhesion deficiency in an 18-year-old girl and a brief literature review.

Keywords: CD 18, leukocyte adhesion deficiency, periodontitis

INTRODUCTION

The immune system is a magnificent alliance between cells and proteins that work together to provide defense against infection. When this alliance is disturbed, this encounters a disease. These disturbances can be in the form of primary immune deficiencies. One such immunodeficiency is leukocyte adhesion deficiency (LAD 1), an autosomal recessive disorder.^[1] LAD 1 is estimated to occur in 1 per million people worldwide.^[2]

The present paper reports a rare case of LAD in an 18-year-old female patient who had presented with oral manifestations.

CASE REPORT

Clinical findings

An 18-year-old young female patient presented with a chief complaint of pain in the gums since two months. She revealed a history of pain which was gradual in onset, intermittent in nature, throbbing type, non-radiating, aggravated on taking food, and relieved gradually. On extra oral examination, both right and left submandibular lymph nodes were palpable with a size of 1 × 1 cm, and were non tender, soft in consistency [Table 1].

Intraoral examination showed pallor of buccal, labial, and lingual mucosa. Gingival and periodontal status revealed an erythematous, edematous marginal, and attached gingiva with erosive areas associated with loss of interdental papilla

and generalized gingival recession. On palpation bleeding on probing was noticed with generalized periodontal pockets and furcation involvement [Figure 1].

Based on the chief complaint and history and on considering clinical findings, we provisionally considered it to be desquamative gingivitis associated with aggressive periodontitis.

Diagnostic assessment

The patient was advised for radiographic and hematological investigations. Orthopantomograph revealed generalized horizontal bone loss and furcation involvement in all first and second molars [Figure 2].

On the recall visit, clinically the lesions were still persistent. She was again advised for a blood workup to assess the state of anemia and leukocytosis. But white blood cells count and, in particular, neutrophil count were still high.

Based on the clinical findings and laboratory investigations, a diagnosis of primary immunodeficiency was considered. So,

Figure 1: Intraoral images depicting erythematous gingiva

the patient was advised for advanced laboratory investigations to assess the immunoglobulins and lymphocytes using immunoturbidimetry and flow cytometry, respectively [Table 2].

Therapeutic intervention and follow-up

Symptomatic management using topical anesthetic gel was advocated, and iron supplements were also prescribed to improve her hemoglobin levels. Oral prophylaxis was carried out with the appropriate use of antibiotics. Further clinical follow-up was hindered as the patient suffered from grave gastrointestinal tract infections and was under physician supervision at higher centers.

Considering the history and clinical findings and based on the laboratory findings, it was diagnosed as leukocyte adhesion deficiency type 1(LAD 1).

DISCUSSION

Interaction of leukocytes with vascular endothelial cells plays an important role to migrate the defense cells to the site of insult. This mechanism takes place in four steps: rolling, slow adhesion, firm adhesion, and transmigration.^[3,4]

LAD I is caused by mutations in ITGB2 (integrin beta-2), the gene located at 21q22 β 2 integrins, there by affecting the third phase of adhesion cascade.^[5]

LAD 1 subtypes include severe, moderate, or variable. In severe form, less than 2% of CD18- expressing neutrophils. In moderate form, 2-30% of CD18-expressing neutrophils in which patients survive childhood with recurrent infections and mortality was reported by 40 years.^[6,7]

Clinical features of leukocyte deficiency type 1 are delayed separation of the umbilical cord with severe omphalitis and recurrent severe infections that usually affect lungs, skin, and gingiva in children. The absence of pus at the infection site is the characteristic of LAD 1.^[8] Most frequently isolated microbes from these patients are Staphylococcus aureus and gram-negative pseudomonas.^[9]

Oral manifestations include oral ulcers, severe periodontitis, and gradual loss of permanent teeth. LAD

Figure 2: Panoramic radiograph reveals generalized horizontal bone loss

Table 1: Timeline of history

Age of the patient	18 years
Pain in gingiva	2 months
Past medical history	No relevant history
Family history	Parents consanguineous marriage

Table 2: Laboratory investigations of patient

Investigation	Result
Hemoglobin	7.7 gm%
Total leukocyte count	25.5 $10^3/\mu$ l
WBC count	17,800 cells/cumm
Neutrophils	77%
Lymphocytes	21%
ESR	75 mm/hour
Absolute lymphocyte count	4.9103/ μ l
Absolute CD3 count (T cells)	4277 cells/ μ l (87.24%)
Absolute CD 3 + CD4 + counts	1970 cells/ μ l
CD4%	40.19%
Absolute CD 3 + CD8 + counts	2098 cells/ μ l
CD8%	42.79%

sub gingival microbes are dissimilar to localized aggressive periodontitis.

Diagnosis is usually made based on clinical presentation, increased leukocyte count on laboratory investigations, and absence of CD 18, CD 11a, CD 11b, and CD 11c on flow cytometry analysis. The gold standard for diagnosis is the identification of a mutation in the ITGB2 gene by genetic analysis. Cordocentesis can also establish the diagnosis as leukocytes express CD18 on their surface from 20 weeks of gestation.^[10]

In this deficiency syndrome, we as dentists cannot change the root cause but can help the patient to lead a better life by providing supportive measures. In this case, the supportive treatment helped the patient, and the results were satisfactory.

CONCLUSION

Though LAD is rare, it should be considered a differential diagnosis when we come across patients with persistent clinical

signs which are recalcitrant to symptomatic management and periodontal therapy.

Declaration

Patient consent was obtained to use the relevant clinical details and images for the scientific publication without revealing the identity.

canals were categorized into different types as suggested by Ossenberg and this was assessed on the sagittal section. The diameter of retromolar canal at their exit and distance of retromolar foramen from the 3rd molar was measured on the axial sections. The results were tabulated and statistically analyzed.

Results: Of the 125 subjects examined, 46 subjects were found to have retromolar canals. Of the 250 sites examined, 54 sites presented with retromolar canals with an incidence of 21.6%. Majority of the canals were of the Type A (79.6%) category followed by Type B canals((20.3%). The diameter of the canal varied from 0.5mm to 1.4mm. The distance of the retromolar canal from the anterior border of the ramus was variable and not concentrated in a particular region.

Conclusion: An incidence of 21.6% compulsively justifies the need to recognize these anatomic variants in surgical procedures involving the retromolar area. It is important for radiologists to possess adequate knowledge on the presence and frequency of these retromolar canals and incorporate them in the interpretation reports to alert the surgeon.

Neuroquantology 2022; 20(16): 5340-5348

Introduction

Anatomical variations are defined as normal flexibility in the topography and morphology of body structures. The retromolar canal is one such anatomic variant, classically described as a canal that branches off the inferior alveolar canal behind the 3rd molar and follows a recurrent path, curving in a posterosuperior direction to open into the retromolar fossa through the retromolar foramen, which is usually located on the alveolar and central part of the retromolar trigone. The retromolar fossa or trigone is a triangle-shaped region anteriorly limited by the third molar, medially by the temporal crest, and laterally by the anterior border of mandibular ramus.¹The constituents of these canals include neurovascular bundle originating from the inferior alveolar nerve, striated muscle fibers, thin myelinated nerve fibers, numerous venules and a muscular artery.²

Various imaging modalities such as panoramic radiography, computed tomography, cone beam computed tomography have been used to detect and evaluate these anatomical variations. However, Orthopantomographs (OPGs) provide primary and significant overview of the oral and maxillofacial region. Two

dimensional radiographic modalities like OPGs fail in the proper presurgical evaluation of the anatomical structures in the buccolingual aspect and crosssectional slices. OPG's also fall short in obtaining reliable measurements, and other factors which influence the diagnostic quality of two dimensional imaging such as patient positioning, magnification distortion and superposition of the anatomical structures are a major challenge to the clinician to evaluate these fine anatomical structures such as retromolar canals ,mandibular incisive canal, accessory mental foramen, accessory mandibular canal, etc.^{2,3}

In the recent times to overcome all these challenges Cone beam computed tomography (CBCT) technology can be used as a substantial modality of maxillofacial imaging extensively as it shows three-dimensional (3D) images of dental structures with clear structural images of high accuracy on which measurements can be easily made.³

There is variation in distribution of these anatomical variations in individuals with different racial and cultural backgrounds hence there is need to examine these canals anatomical variants to deliver quality patient care. This study was done to evaluate the retromolar region for the presence of retromolar canals in a subset of Indian

5341

population by CBCT imaging and to measure the distance from the distal alveolar crest of the 3rd molar to the exit point of retromolar canals

Materials and method

The retrospective study was done in the department of Oral medicine and Radiology after obtaining ethical approval from institutional ethics committee. A radiographic cross sectional study was designed and 125 CBCT images of the mandible were retrieved from the archival records of a CBCT centre (Fig 1). All images of subjects above 18 years were included and CBCT scans displaying developmental disorders, abnormal morphology resulting from trauma and pathologic conditions that potentially affected the area of interest and CBCT images of patients with history of surgery in the region of interest were excluded.

The images were taken with the Kodak 9300C CBCT machine with the following exposure parameters, tube voltage- 90 kVp, tube current - 5 mA and exposure time - 14 seconds. A cylindrical shaped field of view (FOV) measuring 40 x 50 mm with a voxel size of 200 microns will be used will be used for imaging.

The sagittal, coronal and axial images reconstructed from the projection data was used for assessing the retromolar canals. The images were examined under standard viewing conditions and exported and saved in a jpeg format. Copies of CBCT images was made, adjusted and exported to Microsoft Office PowerPoint to create a separate file set for observer evaluation. The file set did not contain any demographic data, and the images were assigned serial numbers. Images were examined by 2 observers; the first observer reviewed the images after an interval of one week. Type of retromolar canals evaluated was as shown in Fig 2.

Type A, The retromolar canal branches off the mandibular canal distal to the 3rd molar and courses superiorly to open into the retromolar fossa.

Type B The retromolar canal courses between the retromolar fossa and the radicular portion of third molar.

Type C The retromolar canal originates from the mandibular foramen in the ramus, it courses anteroinferiorly and then anterosuperiorly to open into the retromolar fossa.

The region of exit of retromolar canals in the retromolar fossa was noted on coronal sections by dividing the retromolar fossa into the buccal half and lingual half (Fig 3). The width at the point of origin from the mandibular canal and the width at the point of exit in the retromolar fossa were measured in sagittal sections. The distance from the distal alveolar crest of the 3rd molar to the mesial aspect of the exit point of all the 3 types of retromolar canals was also measured on sagittal sections.

The data was tabulated and statistically analyzed using SPSS statistical software version 20.0 of IBM, Chicago, USA with Chi-square and Fisher's exact test. Chi square test was used to assess the distribution of retromolar canals based on age, and Fischer's exact test was used to assess the distribution of retromolar canals based on gender and side of occurrence.

Results

125 CBCT images were obtained from a CBCT centre in Bengaluru, these subjects had underwent CBCT examination as a part of their routine radiographic examination . These images were obtained retrospectively analyzed for the presence and course of retromolar canals.

CBCT images of 125 subjects were examined bilaterally for the presence of retromolar canals, hence a total of 250 sites were examined. Out of 125 subjects examined, 46 subjects were found to have retromolar canals. Out of 250 sites examined, 54 sites

presented with retromolar canals. Thus an incidence of 21.6% was noted in the present study which is similar to the incidence reported in CBCT studies conducted in various countries such as Brazil, Switzerland and Turkey (24.6%,-25.6%,26.7% respectively)

Discussion

Retromolar canals need consideration in surgical procedures involving the posterior mandible such as third molar impactions, osteotomy and bone harvesting procedures. Complications such as sensory deficits hemorrhage and traumatic neuroma may arise in the absence of recognition of these variants. The impingement of the neurovascular bundle in the retromolar fossa from prosthetic appliances in the elderly due to the resorption of alveolar bone may result in patient discomfort. These retromolar canals may act as an alternative route for nerve fibers in the posterior mandibular region and evade anesthetization during routine mandibular blocks.¹

Patil et al found that out of the 160 subjects examined, 116 (72.5%) subjects presented with RMCs. It was found that 44 out of 72 males (45%) and 72 of 88 (68%) females presented with retromolar canals. Type B was the most common type. Based on the results of this study, retromolar canal should be considered as a normal anatomical variation rather than a rare finding. The incidence rates of retromolar canals were determined according to gender, location, and type of RMC.⁴ Siddiqui et al found retromolar foramen/canal in 6 mandibles (17.14%), bilaterally in 2 mandibles and unilaterally in 4 mandibles and concluded that retromolar foramen /canal is of profound clinical importance.⁵

de Gringo et al assessed the presence and characteristics of the retromolar canal and association with mandibular molars using cone-beam computed tomography (CBCT). They

found 24.5% prevalence of the retromolar canal. The oblique trajectory was the most common (33.3% on the right side and 50% on the left side).⁶

de Freitas et al evaluated the prevalence of retromolar canals in cone beam computed tomography (CBCT) images and to correlate it with their possible clinical repercussions. They found prevalence of retromolar canals was observed in 15 patients (5.0%), of which 06 were in males and 09 in females.⁷

Full understanding of the anatomy of the mandibular canal and its variations, such as bifid canals, foramina and RMC have great importance in the planning and execution of surgical and anesthetic procedures. Regarding anesthetic procedures, the presence of alterations in the mandibular canal and RMCs may result in anesthetic failures, since such canals may exit through accessory foramina and contain a neurovascular bundle. Failure to achieve adequate anesthesia may therefore be observed when performing the inferior alveolar nerve block for procedures in the region of the last mandibular tooth. Studies on the incidence of RMC are important to prevent failures in regional anesthesia of the inferior alveolar nerve and buccal nerve fibers as well as to minimize the occurrence of accidents and complications in the posterior region of the mandible.⁷

The diameter of the retromolar canals were found to be ranging from 0.5mm to 1.4mm with an average of 0.62mm. The diameter of RMC has been reported to range from 0.2 mm to 3.29 mm in literature. Males have been reported to have larger diameters of RMC, which can be explained by the fact that male mandibles are usually larger than in females.

5343

The drawback of present study was smaller sample size. Further studies are needed with larger sample size and different racial group.

Conclusion

In the present study out of 125, 46 subjects were found to have retromolar canals. Of the 250 sites examined, 54 sites presented with retromolar canals. The majority of retromolar canals in the present study belonged to the Type A (79.6%) category followed by Type B (20.3%). The diameter of the retromolar canals were found to be ranging from 0.5mm to 1.4mm with a mean of 0.62mm. Distance of the retromolar canal from the anterior border of the ramus was variable and not concentrated in a particular region (ranged from 3 -19.1 mm with an average of 9.08 mm) .

Abstract

Background: Leukoplakia is the most common potentially malignant disorder of the oral mucosa. Latest developments in the field of molecular biology have greatly increased our knowledge of the role of various bio markers in carcinogenesis and prognosis of precancerous and cancerous lesions.

Aim: The present study aims to assess the expression of CD44 in saliva of subjects with leukoplakia by quantitative Real Time-polymerase chain reaction.

Methodology: 30 subjects with leukoplakia (clinically and histopathologically confirmed) and 20 healthy controls were included in the study. Quantitative real time PCR was run on the salivary samples of these study subjects.

Results: An individual pattern of down regulation of CD44 was noted in 60% of the subjects with leukoplakia and upregulation was noted in 90% of controls by absolute quantification method. The gene fold expression ratio by relative quantification method between subjects with leukoplakia and controls delta ct method was found to be $5.777/5.827 = 0.9914$ and by double delta ct method was found to be $28.4151/28.0694 = 1.0123$. No statistical significant difference was noted in the expression of CD44 and grades of epithelial dysplasia.

Conclusion: Although an individual pattern of down regulation of CD44 was noted in subjects with leukoplakia, the gene fold expression ratio between subjects with leukoplakia and controls by both the methods was approximately 1 suggesting no difference in the gene fold expression ratio between subjects with leukoplakia and controls. CD44 was not found to be a reliable marker in determining the malignant transformation of leukoplakia.

Keywords: Leukoplakia, CD44, q RT-PCR, Bio-markers, Saliva.

Introduction

Oral cancer is the 15th most prevalent cancer with the age standardized incidence rate of 3.9 per 100,000 populations worldwide. The Indian subcontinent accounts for one-third of the world burden of this malignancy. Oral cancer is the most common form of cancer and accounts for increasing number of cancer related deaths among men in India.¹ Oral cancer mostly occurs in the buccal mucosa and of the Indian population as compared to the western countries where oral cancer mainly occurs in the lateral border of the tongue. This may be due to the fact that the Indian population is more prone to use of smokeless variety of tobacco.²

Leukoplakia is the most common potentially malignant disorder of the oral mucosa. The annual incidence of oral leukoplakia among subjects greater than 15 years of age ranges from 0.2% to 11.7% in different populations of India.³ It is defined by the World Health Organization in 2005 as a “A white plaque of questionable risk having excluded (other) known diseases or disorders that carry no increased risk for cancer”. In an explanatory note it has been explicitly stated that the term leukoplakia is unrelated to the absence or presence of epithelial dysplasia.⁴

Studies have shown that dentists and other health care providers are in a tremendous need of systematic educational updates in oral cancer prevention and early detection.²

The ability to clinically predict malignant transformation is difficult.⁵ A number of diagnostic kits have been developed for the early detection of oral cancer namely OralCDx Brush Biopsy, ViziLite Plus, toluidine blue staining etc. Although these tests can assist in identification of dysplastic features or frank malignancy, they are associated with either false positive or false negative results and are not conclusive.⁶ Hence a need for confirmation of their malignant potential by histopathological evaluation arises. However histopathological diagnosis has limited prognostic value and disadvantage of patient discomfort and fear.⁵

A latest development of various bio-markers in carcinogenesis of precancerous and cancerous lesions helps in prediction of rate of malignant transformation and prognosis of the lesion.⁶ These biomarkers have generally been detected either in the serum or tissue

specimens. Some of these biomarkers can also be detected in saliva as saliva may be considered as a reflection of serum.⁷ Various biomarkers namely Ki-67, argyrophilic nucleolar organizer regions, p53 helps to predict the malignant potential of and as a prognostic tool in oral cancer.⁸

CD44 is a biomarker expressed as a cell surface glycoprotein by a large variety of tissues such as colorectal tissues, urinary bladder, lungs head and neck epithelia etc. It is also released from mast cells, lymphocytes, and hence are detectable in circulation as well. CD44 acts as a receptor for the extracellular matrix components namely hyaluronate, laminin, collagen etc.^{9,10}

Studies have evaluated the role of CD44 in tissue samples of HNSCC with the help of various methods such as immunohistochemistry, PCR and flow cytometry. An increased expression of CD44 in saliva of subjects with HNSCC as compared to normal study subjects has been reported in four studies. However one study found no difference in expression of CD44 in both HNSCC and normal study subjects. This was attributed to the fact that HNSCC is a multifactorial disease which involves a number of risk factors.¹¹

There are limited studies on the expression of CD44 in saliva of subjects with leukoplakia. Hence this research was done to assess and compare the levels of CD44 in saliva samples of soluble CD44 in saliva of leukoplakia group with and controls by quantitative Real Time-polymerase chain reaction (RT-PCR) technique and to evaluate the correlation between the salivary soluble CD44 and epithelial dysplasia in subjects with leukoplakia.

Materials and method

Study design

This case control study was done in the department of Oral medicine and Radiology after obtaining the approval from institutional ethics committee.

In this study with Null hypothesis $H_0: m_1 = m_2$ vs. Alternative hypothesis $H_a: m_1 = m_2 + d$ where d is the difference between two means and n_1 and n_2 are the sample size for Group I and Group II such that $N=n_1+n_2$. The ratio $r=n_1/n_2$ is considered whenever the researcher needs unequal sample size due to various reasons, such as ethical, cost, availability etc.

Sample size estimation

In this study for an outcome variable CD44s with difference of 1.0(SD=1.40), 90% statistical power and 5% statistical significance, the total sample size of 50 can be derived by systematic random sampling.

Then the total sample size for the study is as follows

$$N = \frac{(r+1)(Z_{\alpha/2} + Z_{1-\beta})^2 \sigma^2}{r d^2}$$

Where Z_{α} is the normal deviate at α level of significance(Z_{α} is 1.96 for 5% level of significance and 2.58 for 1% level of significance) and $Z_{1-\beta}$ is the normal deviate at $1-\beta$ % power with β % of type II error(0.84 at 80% power and 1.28 at 90% statistical power). $r=n_1/n_2$ is the ratio of sample size required for two groups, generally it is one for keeping equal sample size for two groups, If $r=0.5$ gives the sample size distribution as 1:2 for two groups. σ and d are the pooled standard deviation and difference of means of two groups.

Methodology

Total 50 samples were divided into, 30 subjects with leukoplakia (clinically and histopathologically confirmed) and 20 healthy controls groups.

Non stimulated salivary sample was collected from both the groups and subjected for investigation. The expression of CD44 in saliva of subjects with leukoplakia was assessed by quantitative Real Time-polymerase chain reaction (PCR) method for both the groups.

Results

In the present study, the difference in CD44 gene fold expression ratio between subjects with leukoplakia and controls was calculated by the following two methods; Delta ct method: Delta ct mean of the subjects/ Delta ct mean of controls and Double delta ct method: RQ mean of subjects/ RQ mean of controls. In both the above mentioned methods, values <1 indicate that the gene fold expression of cases are less than controls where as values >1 indicate that the gene fold expression in cases is more than controls. Values =1 indicate no change in gene fold expression.

In the present study, the gene fold expression ratio by delta ct method was found to be $5.777/5.827= 0.9914$ and by double delta ct method was found to be $28.4151/28.0694=1.0123$. As the ratio between subjects with leukoplakia and controls was found close to 1 it can be interpreted as gene fold expression between the cases and controls is not significant / or no change is observed between the subjects with leukoplakia and control group in terms of gene fold expression.

Table 1 and 2 indicated distribution of subjects based on gender, age. Males were 27 with leukoplakia and 17 in control group whereas 3 each with leukoplakia and control group (Table 1). Subjects were evaluated with age range of 21-40, 41-60, and >60 (table 2).

Table 3 indicates distribution leukoplakia lesions based on their clinical form and location. Highest leukoplakia form was homogenous one 24 (Buccal mucosa) and 4 as non homogenous one (4 in buccal mucosa, 1 each in soft palate and gingival). There was 18 cases with no dysplasia, 6 mild for homogenous variety. In non homogenous variety, 3 were no dysplasia, 2 were mild and 1 moderate dysplasia (Table 4).

Based on the quantitative expression of CD44 gene, subjects with leukoplakia had 12 cases of upregulation and 18 with down regulation. In control group there was 18 upregulation and 2 down regulation (Table 5). CD44 gene expression based on clinical forms of leukoplakia lesions indicated in table 6 with highest cases with homogenous compared to speckled type.

Table 7 indicates CD44 gene expression based on degree of dysplasia. There was 9 cases diagnosed as no dysplasia, 3 with mild and 1 with moderate dysplasia.

Discussion:

Oral cancer is the most common type of cancer of the head and neck, with an annual worldwide incidence of 300 000 cases. The disease is an important cause of death and morbidity, with a 5-year survival of less than 50%. Most of the oral cancers arise from potentially malignant disorders. Leukoplakia is the most common potentially malignant disorder of the oral mucosa. The prevalence of oral leukoplakia ranges from 0.4% to 0.7% of the population worldwide.^{1,3}

The present study evaluates and compares the CD44 gene for diagnosis of leukoplakia. In the present study 16% of the subjects presented with epithelial dysplasia. The frequency of epithelial dysplasia in leukoplakia varies between < 1 and > 30% across literature. The lowest frequency of 0.3% was reported in a population-based study in India in which all clinically diagnosed leukoplakias were biopsied and a very small portion of the subjects presented with epithelial dysplasia.

In the present study, the age of the subjects with leukoplakia ranged between 25-77 years. This is in accordance with two Chinese^{12,13} studies in which the age of subjects with leukoplakia ranged from 21-84 years and 24-83 years respectively. In the present study the mean age of subjects with leukoplakia was found to be 48.4 years which is in similarity with studies conducted in India¹⁴, where in the mean ages were found to be 48, 47, years respectively. However studies in countries like Brazil¹⁵, China¹³, Taiwan¹⁶, Netherlands¹⁷ reported a slightly higher mean age of the subjects ie. 54 years, 55 years, 52 years, 51 years respectively.

In the present study, most of the subjects with leukoplakia were in the 5th decade of life. An extensive early survey in India and studies conducted in China¹³ and Taiwan¹⁶ reported a peak incidence of leukoplakia in the fifth decade of life in concurrence with the present study.

It has been reported that the age at which leukoplakia occurs in an individual is an important risk factor that affects the malignant outcome of leukoplakia. The malignant potential of leukoplakia was assessed in a Chinese study¹³ and it was found that the malignant transformation rate of leukoplakia was 72.6% higher in the elderly patients as compared to the younger age groups.

A Hungarian study¹⁸ reported a peak incidence of leukoplakia in the 6th decade of life. This could be due to the prolonged duration of exposure to tobacco amongst the older age groups.

Tobacco usage is the most common etiological factor in the development of leukoplakia. In the developing world, tobacco and areca nut use, either alone or in combination, accounts for the vast majority of leukoplakias. In the present study, 90% of the subjects were smokers and 6% of the subjects used smokeless tobacco habit alone and 3% of subjects used both. The findings of the present study are in agreement with previous reports from Brazil¹⁵, Hungary.¹⁸

C`ema et al evaluated the role of pan-CD44 protein expression in leukoplakia tissues. They concluded that CD9 antigen expression in the exosomes of the oral epithelium explained the intercellular flow of SolCD44 and other fluids in the leukoplakia area.¹⁹ Franzmann et al assessed salivary soluble CD44 (solCD44) expression in HNSCC patients and concluded that, salivary solCD44 ELISA seems to effectively detect HNSCC at all stages.²⁰ Gadge et al stated that among CD44s and its variant isoforms, v5, v6, variant isoform v6 may serve as a marker in detecting high-risk leukoplakias.²¹

Ghazi et al found that diagnostic test's accuracy for identification of OSCC and dysplastic leukoplakia from non-dysplastic leukoplakia and normal tissues and recognition of OSCC from dysplastic leukoplakia showed optimum sensitivity and specificity.²²

Eighty percent of the study subjects presented with a homogenous variety of the disease whereas 17% of subjects presented with a speckled variety of leukoplakia. One subject i.e., 3% presented with verrucous variety of leukoplakia.

In the present study 16% of the subjects presented with epithelial dysplasia. The frequency of epithelial dysplasia in leukoplakia varies between < 1 and > 30% across literature. The lowest frequency of 0.3% was reported in a population-based study in India in which all clinically diagnosed leukoplakias were biopsied and a very small portion of the subjects presented with epithelial dysplasia.

CD44 expression has been assessed in the head and neck region by various methods such as immuno-histochemistry, western-blot analysis, flow cytometry and polymerase chain reactions in various mediums such as the tissue samples, serum and saliva as a diagnostic and prognostic bio-marker. Discrepancies in the expression of CD44 are probably due to the use of different immunohistochemistry protocols and also due to the differences in the patient population examined.

It has been observed that in epithelia that show loss of integrity such as in HNSCC, low solCD44 levels are initially observed in serum and saliva, which leads to the hypermethylation of the CD44 promoter resulting in increased expression of CD44. Hypermethylation status together with increased CD44 levels may be used as an early marker for HNSCC in cases of oral potentially malignant disorders such as leukoplakia.

Hence, an attempt was made to assess the expression salivary soluble CD44 in subjects with potentially malignant disorders such as leukoplakia. The present study showed no change in CD44 gene fold expression when compared between subjects with leukoplakia and controls although an individual pattern of down regulation and up regulation was noted in the cases and the control population. The results of the present study could not be compared with studies in literature as no studies have assessed the expression of CD44 in serum and saliva samples of subjects with leukoplakia.

Further validation of role of CD44 expression in potentially malignant lesions can be substantiated by determining the role of CD44 in tissue samples of oral leukoplakia. The deterministic establishment of role of CD44 observed in tissue samples, would pave way for further studies in serum in saliva samples. This would help in clarifying the role of CD44 in predicting the malignant potential of premalignant lesions .Studies investigating the effect of smoking cessation and reversal of the lesion on the levels of CD44 are strongly recommended. Success in any of these areas could revolutionize oral cancer screening, by providing a simple and reliable measurement of oral cancer risk assessment that can alert primary care providers, dentists, and other frontline screeners to individuals most in need of skilled oral exam at a stage when the process can be more easily treated or perhaps even reversed with behavioral modification.

Conclusion

It was concluded that, an individual pattern of down regulation in 60% of the cases with leukoplakia and up regulation was noted in 90% of the controls by absolute quantification method, and the gene fold expression ratio by relative quantification method between subjects with leukoplakia and controls by delta ct method was found to be $5.777/5.827= 0.9914$ and by double delta ct method was found to be $28.4151/28.0694=1.0123$. There was no difference in the gene fold expression ratio of CD44 between subjects with leukoplakia and controls as the gene fold expression ratio value between subjects with leukoplakia and controls was found to be approximately 1. No statistical significant difference was noted in the expression of CD44 and grades of epithelial dysplasia. CD44 were not found to be a reliable marker in determining the malignant transformation of leukoplakia.

Abstract

Introduction: The success of prosthodontic procedures can be accurately determined by the exact replication of the patient's condylar path using a semi-adjustable articulator. It allows the clinician to determine the morphology of the occlusal surfaces in relation to the condylar pathway during mandibular movements. If condylar guidance is not exactly registered, it might result in occlusal interferences during movements of the mandible and lengthen chairside adjustment time, which is inconvenient for the patient and dentist.

Materials and methods: A total of 20 dentulous patients from 20 to 30 years of age group attending the department of prosthodontics at Sibar institute of dental sciences were selected for the study. Alu wax and jet bite were used to obtain the protrusive interocclusal record (PIR). Protrusive records were then used to program the semi-adjustable articulator to obtain HCGA values on both sides. Using the same protrusive records CBCT radiograph was taken. Radiographic images were traced on tracing paper and HCGA values were measured using Frankfort's horizontal reference line (the line connecting porion and orbitale) and the mean curvature line (most-superior and most-inferior points of the curvatures) on both sides using a protractor. The data were analyzed by paired sample t-tests and Pearson's correlation tests.

Results: There was no significant difference between the right and left sides in the clinical and radiographic methods using Alu wax PIR. In the clinical method utilizing jet bite PIR, the right side had significantly higher HCGA values than on the left side. On CBCT, no such differences were found.

Conclusion: CBCT horizontal condylar guidance angle values were higher than those obtained using the clinical method by using both records. Values obtained from both the methods, i.e., protrusive interocclusal record and cone-beam computed tomography, were compared and correlated.

Keywords: Alu wax, Jet bite, Protrusive interocclusal record (PIR), Horizontal condylar guidance angle (HCGA), Frankfort's horizontal plane (FHP), and Cone Beam Computed Tomography (CBCT).

Introduction:

Prosthetic dentistry intends to regain missing tooth morphology and re-establish an ideal occlusion in accordance with the stomatognathic system of the patient. Among five factors that influence the laws of articulation as given by Hanau, the most important factor in establishing balanced articulation and the most predominant consideration in any patient's oral rehabilitation is condylar guidance. ⁽¹⁾According to GPT9, Condylar guidance is defined as the mandibular guidance generated by the condyle and articular disk traversing the contour of the articular eminence.

Research into the mechanism of condyle and efforts to register movements of the mandible began in the 18th century. ⁽²⁾ The "protrusive wax check bites" described by Christensen in 1905 and the graphic approach introduced by Gysi in 1908 were the first methods used to record the HCG. ⁽¹⁾ Since then, many authors have conducted research to determine the HCG using a variety of approaches and compared the variability between different registration techniques, articulator systems, and recording materials.

There are three basic methods for obtaining HCG: (1) Intraoral methods, (2) Extraoral methods, and (3) Radiographic methods. Intraoral methods such as protrusive wax interocclusal records, leaf gauge, Lucia jig, and intraoral tracers can be utilized to determine the mandible's centric and eccentric relationships. ⁽³⁾ Intraoral record regardless of the type of material employed, represents only one position along the condylar path and horizontal condylar guidance angle (HCGA) varies with the degree of protrusion. ⁽⁴⁾ Even if the registration methods are followed precisely, inaccuracies may occur due to friction interference of smooth movements between the articulator's condylar components. ^(3,5) Extraoral methods include radiographs and pantographs. Boos attempted to record the condylar path using a temporomandibular radiograph in 1951 to identify condylar guidance. During the 1970s to overcome the disadvantages of clinical approaches, authors such as Corbett et al. (1971), Ingervall (1974), Christensen and Slabbert (1978) proposed radiographic methods of recording the HCG.

Radiographic techniques include lateral cephalograms, panoramic radiographs, and computed tomograms. ⁽⁵⁾ They are more accurate as it includes stable bony landmarks and can be easily standardized. ^(2,6,7) Although panoramic radiographs and lateral cephalograms provide a two-dimensional (2D) image of the temporomandibular joint (TMJ), ⁽⁵⁾ CBCT, as a more advanced cutting-edge technology, provides three-dimensional (3D) multiplanar sections without superimposition, allowing the glenoid fossa and articular eminence to be clearly seen from the surrounding structures. ^(5,8) Tomography scans, on the other hand, have been safer, requiring less radiation exposure and becoming more effective since the introduction of CBCT, resulting in its outspread usage in dentistry. ⁽⁹⁾ However, the limitations of CBCT include the high cost of the equipment. ^(10,11)

Most of the studies used panoramic imaging and lateral cephalograms for recording HCGA. ⁽²⁾ There are very few studies comparing clinical and radiographic procedures employing CBCT. So, the goal of this study was to compare HCGA values obtained from protrusive interocclusal records of two different materials (Alu wax and Jet bite – polyvinyl siloxane) with the CBCT (panoramic section) radiography technique.

Materials and Methods:

The study was conducted in the Department of Prosthodontics, Sibar institute of dental sciences, Guntur, Andhra Pradesh, India. Written consent was obtained from all the patients. Twenty patients aged between 20 and 30 years with a full complement of dentition fulfilling the following criteria were selected.

Inclusion Criteria: Inclusion criteria are Angle's Class I molar and incisal relations, individuals with impacted third molars, absence of crowded or maligned teeth, good oral hygiene, and periodontal status.

Exclusion Criteria: Exclusion criteria are facial or skeletal malformations, Poor neuromuscular coordination, and Individuals with severe Temporomandibular joint disorders (myofascial pain dysfunction syndrome, osteoarthritis, internal derangements, rheumatoid arthritis, ankylosis, tumors, trauma, and developmental disorders), deteriorating general health.

A) Making of impression & obtaining casts:

Diagnostic impressions were made using a stock tray (perforated stainless steel) using irreversible hydrocolloid impression material. The impressions were rinsed, dried, inspected, and disinfected using 2% glutaraldehyde (Cidex) for 10 minutes and the cast was poured with type III dental stone. Six wedge-shaped notches were made at the top of the maxillary cast for the split cast where two notches toward the outer edge of the posterior border, two in the first molar region, and two in the lateral incisor region.

B) Face bow transfer

Facebow transfer was done using a Hanau spring bow and this assembly was transferred to the articulator using indirect mounting transfer and the casts were mounted (Figure 1 and Figure 2).

C) Interocclusal bite registration method:

To obtain records initially, the patient was trained to move the mandible forward till the teeth are in an edge-to-edge relationship. Two bite registration materials were used, i.e., alu wax and jet bite (polyvinyl siloxane). To obtain a wax record a two-sheet thick alu wax rim is adapted to the maxillary arch and the patient was asked to move the teeth into edge-to-edge relation (Figure 3 and Figure 5). This record was transferred to the articulator (HANAU Wide-View Articulator). Protrusive relation was assessed and reconfirmed before setting the horizontal condylar inclinations, and locknuts were tightened. In all the cases, the articulator was programmed by a single operator only.

D) Programming of articulator:

In this study, Hanau articulator was modified to obtain accuracy of condylar guidance. The articulator has a numerical scale condylar track with 5° increments. A protractor with angulations from 0° to 60° was mounted to the condylar shaft for more precise values. The protractor's center was set to align with the condylar shaft's center. While measuring the angle, the protractor's 0° was aligned with the 0° pointer. A 23-gauge orthodontic wire was used to make an L-shaped extender and was attached to the zero-reference line. While interpretation, if the protractor's pointer was at 0.5mm or more, the higher value is considered as the reading, and if the pointer was at less than 0.5mm, the lower value is considered. To determine the horizontal condylar guidance articulator condylar locks were loosened, and the protrusive record was positioned on the mandibular cast. The maxillary cast was placed

Dr. L. KRISHNA PRASAD

DEAN

SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

on the imprints of the protrusive record. The upper member of the articulator was adjusted so that the maxillary cast would seat into the indentations of the split cast, and the two parts were held together firmly (Figure 4 and Figure 6). Readings of the condylar guidance angle values on the right and left sides of the articulator were recorded. Same procedure was repeated three times until two similar values are obtained (Figure 7). The condylar screws were tightened, and the right and left condylar readings were recorded and calculated.

E) Radiographic method:

CBCT was obtained with the patient's mandible in a protrusive position along with bite registration material (Figure 8). Articular eminence and mandibular fossa were identified on both the right and left sides (Figure 9). Tracings were done on the CBCT image, i.e., the Tangent of the Posterior slope of the articular eminence was drawn, a line joining the superior most point of the external auditory meatus (Porion) and the Inferior most point of orbital margin (Orbitale) were marked. This represents the radiographic horizontal condylar guidance angle (Figure 10). The angles between these two lines were evaluated by using a protractor.

Statistical Analysis: Statistical analysis was done using SPSS version 20 software (IBM Corp., Armonk, NY, USA). Descriptive statistics, paired sample t-tests, and Pearson's correlation coefficient tests were done to analyze the study data. Bar charts and matrix scatter plots were used for data presentation.

Results Summary:

Table 1 represents the comparison of horizontal condylar guidance angle values between the right and left sides in both CBCT and clinical method using Alu wax protrusive inter-occlusal record. There were no significant differences between the right and left sides in both the clinical and radiographic methods (Figure 1). Significantly higher horizontal condylar guidance angle values were observed on the right side in the clinical method using jet bite protrusive inter-occlusal record when compared to the left side (Table 2). No such differences were observed in the CBCT evaluation (Figure 2). Comparison of horizontal condylar guidance angle values between CBCT and clinical method using Alu wax protrusive inter-occlusal record was done on right and left sides. Significant differences were noted with higher mean horizontal condylar guidance angle values documented using CBCT compared to the clinical method. Similar observations were made with regard to jet bite protrusive inter-occlusal record using CBCT, demonstrating significantly higher mean horizontal condylar guidance angle values on both the right and left sides.

Table 1: Comparison of horizontal condylar guidance angle values between right and left sides in both CBCT and clinical method using Alu wax PIR

Method	Side	Mean	N	Std. Deviation	Std. Error Mean	t value	P value
Clinical	RIGHT	31.90	10	2.767	.875	0.068	0.948
	LEFT	31.80	10	4.917	1.555		
CBCT	RIGHT	37.00	10	2.160	.683	-0.525	0.612
	LEFT	38.00	10	6.146	1.944		

Paired sample t test; $p \leq 0.05$ considered statistically significant; PIR—Protrusive Inter-occlusal Record

Figure 2: Comparison of horizontal condylar guidance angle values between right and left sides in both CBCT and clinical method using Jet bite PIR

Discussion:

The relationship between the occlusal surface morphology and the condylar path traced during mandibular movements have been well documented. Gysi (1910), Gilis(1926), and Gysi & Kohler (1929) were the first investigators to recognize the importance of determining the horizontal path of condyles while restoring occlusion in patients.⁽¹⁾ HC Gangles range from 5°-55° in studies conducted by various authors. (Zamacona, Otaduy, Aranda,1992., dosSantos Jr, Nelson, Nowlin, 2003., Lundeen, Wirth, 1973., Woelfel, Winter, Igarashi, 1976., Hobo, Mochizuki, 1982).⁽¹²⁾

The oldest method of recording HCGA is by using an interocclusal record.^(13,14,15) It is a widely practiced and accepted clinical method to record horizontal condylar guidance angle values (Posselt,1968.,Mohl,et.al.1988.,Posselt,1968.,Rosensteil,Land,&Fujimoto, J.2006).⁽¹²⁾ Alu wax and Poly vinyl siloxane were chosen as materials of choice to obtain inter-occlusal protrusive records in this study. In comparison to base plate wax, Millstein et al. discovered that adding 0.05 mm thick aluminum laminate between wax wafers loaded with copper particles enhanced accuracy. In comparison to the wax recording materials, the Coprwax aluminum laminated, metalized wax wafer has shown less distortion.⁽¹⁶⁾Breeding and Dixon investigated the compression resistance of numerous elastomeric interocclusal record materials. He stated that interocclusal

Dr. L. KRISHNA PRASAD

DEAN

SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

recording material made of poly vinyl siloxane had the best compression resistance.⁽¹⁷⁾

Another method of recording HCGA used in this study was utilizing radiographs.⁽⁴⁾ Radiographic methods have been demonstrated to record horizontal condylar guidance more precisely than other methods (dosSantos Júnior, Nelson, & Nummikoski,1996., Christensen,& Slabbert, 1978., Gilboa, Cardash, Kaffe, & Gross, 2008). Christensen and slabbert stated that "No radiographically determined sagittal condylar guidance angle corresponded with that acquired using intra-oral records". The angle determined by radiographs had a higher mean value than the clinical data.⁽⁶⁾

The clinical and CBCT radiographic image of the sagittal outline of the articular eminence and glenoid fossae was identified in all 20 subjects. Using Alu wax PIR horizontal condylar guidance angle values between the right and left sides in the clinical method were 31.90° and 31.80°. Using Alu wax PIR horizontal condylar guidance angle values between the right and left sides by CBCT method were 37.00°and 38.00°. Using jet bite PIR horizontal condylar guidance angle values between the right and left sides in the clinical method were 37.00° and 35.40°.Using jet bite PIR horizontal condylar guidance angle values between right and left sides by CBCT method were 40.20°and 39.60°.Comparison of horizontal condylar guidance angle values between the clinical method and CBCT using Alu wax PIR on the right side were 31.90° and 37.00°. Comparison of horizontal condylar guidance angle values between the clinical method and CBCT using Alu wax PIR on the left side were 31.80° and 38.00°. Comparison of horizontal condylar guidance angle values between clinical method and CBCT using jet bite PIR on the right side were 37.00°and 40.20°.Comparison of horizontal condylar guidance angle values between clinical method and CBCT using jet bite PIR on the left side were 35.40° and39.60°.

There was no significant difference between the right and left sides in both the clinical and radiographic methods using Alu wax PIR. In the clinical method utilizing jet bite PIR, the right side had significantly higher horizontal condylar guiding angle values than the left side. On CBCT, no such differences were found. Condylar guidance values recorded using CBCT were higher than those obtained using the clinical method by using both the records.

According to the literature, the right and left eminences rarely have the same slants and contours. Csado et al, Shrestha et al, and Prasad et al found smaller mean differences between the right and left HCG angle in their studies. These values are statistically not significant but clinically and radiographically, the value of HCG angles was higher on the right side as compared to the left side.⁽¹³⁾ Alshali et al. found no statistically significant differences in sagittal condylar inclination values between the male and female groups or between the right and left sides. Sagittal condylar inclination angle decreased with age on both the right and left sides, with statistically significant changes in values for both methods. Godavarthi et al found that the condylar guidance angle for the right and left sides was 38.62°and38.05°respectively, which was statistically insignificant.⁽⁸⁾

Gilboa et al. discovered a positive association between anatomic and radiographic angles for articular eminence inclination, with correlation coefficients of 0.561 and 0.802 for the left and right sides, respectively.⁽¹⁸⁾According to a study by Kaur S et al., the mean difference in the angles of inclination of the inferior border of the zygomatic arch measured by radiographic and anatomic methods was 8 and 8.47 for the left and right

Dr. L. KRISHNA PRASAD
DEAN

sides, respectively.⁽¹⁹⁾

In this study CBCT values are on an average of 6° - 7° higher than the clinical method utilizing alu wax interocclusal record. CBCT values on an average of 3° - 4° higher than the clinical method utilizing Jet bite interocclusal record. Based on this study CBCT values have a moderate correlation with the clinical method utilizing jet bite interocclusal records.

Tannamala et al found a 2° - 4° difference in HCG angle between OPG and the protrusive occlusal record,⁽²⁰⁾ while Shreshta et al found a 9° - 10° difference in HCG angle between CBCT images and the protrusive occlusal record,⁽⁶⁾ and Das et al found no significant difference in HCG angle between CBCT images and the protrusive occlusal record.⁽⁸⁾ Shetty and colleagues also found higher condylar guidance values from the radiograph when evaluating the reliability of programming the articulator using the radiographs and the interocclusal records.⁽²¹⁾ Radiographically determined condylar angles provided greater results than intraoral recording techniques, according to Christensen et al. In a study by Vadodaria, condylar guidance acquired by CBCT was about 10° higher than clinical methods, as evidenced by Jerath⁽¹⁴⁾ et al, Kwon⁽⁹⁾ et al, and Naqash⁽²⁾ et al, who found that HCG angle values acquired from CBCT measurements were 5° - 6° higher than those obtained from protrusive occlusal records.

In general, the results of this investigation show that none of the clinical approaches were found to provide condylar guidance angle values that were comparable to the CBCT. Dimensional changes in materials, in accuracies discovered in the casts, or failure to achieve the desired accuracy of the fit of interocclusal record on the occlusal surfaces are all possible reasons for the drawbacks of the clinical method.⁽²²⁾ According to Muller et al, the removal and placement of the record eventually produce discrepancies. According to Donegan and Christensen the common reason for the inconsistency of intra oral methods is that the horizontal condylar angle changes with the degree of protrusion, regardless of the material selected.^(4,6) According to Ratzmann et al, Intraoral method of recording condylar guidance angle, have inferior levels of reproducibility and are prone to variation in the operator, instrument, and occlusal records.⁽⁶⁾

CBCT scans for condylar measures may be beneficial, especially in the case of complex oral rehabilitations. To corroborate the current findings, substantially higher sample sizes with Condylar Guidance angle values are required to confirm the current findings. This would ease the procedure to establish a predictable occlusal scheme in the prosthetic rehabilitation of patient.

Summary and Conclusion:

Although many clinicians depend on the average condylar guidance angle values ranging from 22° to 65° for the fabrication of the prosthesis, occlusal harmony could not be established since the HCI of the patient did not match with the patient's own values. HCGA values obtained via radiographic techniques can be utilized directly to program the semi-adjustable articulators, eliminating the need for technique-sensitive-dependent clinical approaches which are dependent on the operator or patients' neuromuscular control.

Abstract

The use of efficient local anesthetic is crucial in contemporary dentistry. The majority of young patients who receive local anaesthetic injections feel scared and anxious. Even more concerning is the possibility that uncomfortable child will put off getting the necessary dental treatment and might put off getting it again as adults. Local anesthetic is the primary method of pain management in the field of dentistry, however research is ongoing to identify more creative and effective approaches. Several pharmacological and alternative delivery techniques have been created to alleviate the discomfort connected with local anaesthetic injections. TENS has been proposed as a more convenient and advantageous substitute for traditional LA methods for decreasing anxiety. TENS is described as the direct stimulation of nerves by electrical impulses of brief duration and small amplitude. To explain the mechanism of action of TENS in regulating pain, a number of theories have been put forth, including the Gate Control Theory, Endorphin Release Theory, and Serotonin Release Theory. Hence, the purpose of present review of literature is to discuss the electronic dental anesthesia (EDA)/transcutaneous electric nerve stimulation (TENS) in detail.

Keywords: Pain, Electronic Dental Anaesthesia, Local Anaesthesia, TENS

Introduction: It is crucial to manage pain during both invasive and non-invasive dental procedures because discomfort may cause patients to refuse care or put off getting it altogether.¹ In dentistry, invasive procedures, such as tooth extractions and surgeries, are more frequently associated with pain than non-invasive ones. The use of local anaesthetics is used to prevent and manage pain, and they are thought to be the safest and most effective medications available for these purposes. But because many people are afraid of the needle used when injecting, the act of administering these medications also causes panic in the patients. Even in preverbal children, fear of pain is not unwarranted because untreated pain has a negative impact on health outcomes and is recalled by preverbal children.²

Several methods have been suggested to reduce pain caused by the administration of local anesthetic agents. These include the following: Application of topical analgesics such as amethocaine³, Distraction techniques^{4,5}, Counter irritation⁶, Warming the anaesthetic agents⁷, Adjusting the rate of infiltration by reducing the speed of the injection⁸, Buffering the local anesthetic agent^{9,10}

TENS, also known as transcutaneous electrical nerve stimulation, is a peripheral nerve stimulation technique for pain relief. It's a technique that provides us a promising way to produce dental anesthesia by using a mild amount of electric current and is based on the much-established Gateway Theory of pain control given by Malzack and Wall in 1965.¹¹ TENS has been given U.S. Food and Drug Administration approval.^{12,13} In this mode of therapy, electrodes are used to transmit pulsed electrical current, which is created in one of two ways - direct current or batteries - along the intact skin's surface in order to stimulate superficial nerves and relieve localised pain. TENS is frequently used in the realm of medicine to treat both acute and persistent pain.¹⁴ Purpose of present review of literature is to discuss the electronic dental anesthesia/transcutaneous electric nerve stimulation in detail.

History of TENS: The idea of relieving pain through the use of electricity is not a new thought. Ancient Egyptians applied electrogenic fish to body part of that hurt. Electrostatic generators rose to prominence in the eighteenth century, but by the end of the nineteenth century, their employment had decreased due to the widespread use of other pharmaceutical techniques. Melzack and Wall came to the conclusion in 1965 that electrical stimulation of the nervous system can help stimulate large diameter afferent nerve fibres, hence blocking the transmission of unpleasant sensations via the brain's central nervous system. This was written about in the book "Pain Mechanisms: A New Theory." In clinical studies, it was found that electrical current stimulation of brain inhibitory pathways helped reduce pain. The effectiveness of implants that activated the dorsal column was first evaluated using TENS therapy. TENS was later discovered to be a stand-alone treatment.^{11,13}

Type of TENS: The most common type of TENS utilised in dental practises is conventional TENS. It can be used continuously throughout the day with periodic breaks to prevent skin irritation. AL-TENS can be used for 30 minutes at a time and employs low frequency with high amplitude. Intense TENS therapy uses high-frequency and high-amplitude pulsed current, which is less pleasant and is not frequently employed.¹⁴⁻¹⁶ (**Table no. 1**)

Conventional TENS	The targeted stimulation of A-beta fibres is the justification for using traditional TENS. These afferent neurons have a wide diameter, are non-noxious, and have a low pain threshold. The central nervous system's nociceptive neurons experience an inhibition of activity as a result of TENS stimulation. Pain relief is attained by raising the pulse amplitude in TENS to create a nonpainful paraesthesia below the electrodes. ¹⁵
Acupuncture-Like TENS	AL-TENS functions by stimulating high-threshold peripheral afferent neurons called A-delta fibres. As a result, descending pain inhibitory circuits are activated. As a result of this therapy's activation of numerous muscle afferent nerve fibres, muscle twitching is observed. For pain relief, electrodes are placed over myotomes or trigger points, or at acupuncture points. ¹⁷
Intense TENS	To limit the spread of painful stimuli in peripheral nerves and activate extrasegmental analgesic mechanisms, high-intensity TENS is used to stimulate high-threshold cutaneous A-delta fibres. ¹³

Parts of TENS: Main parts of TENS systems are:

1. TENS unit.
2. Lead wires.
3. Electrodes

TENS Unit: It is a generator of electric pulses. It comes in two forms: "Clinical" model: This is used by dentists in the clinic and generates electricity by being linked to the building's electrical socket. Model "Patient": This is a compact, transportable device that the patient can carry in their pocket or fasten to their belt or outfit. It has a battery inside as a power supply.¹⁸

Dr. L. KRISHNA PRASAD

DEAN

SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

Lead Wires: These establish an electrical connection between the electrodes and the TENS unit.¹⁹

Electrodes: The TENS unit's electric flow is transformed into an ionic current flow in living tissue by the use of electrodes. Both extra- and intra-oral placement of electrodes is possible. There are two types of extraoral electrodes: Flexible electrodes made of silicone rubber impregnated with carbon are attached to the skin's surface with the help of an electrically conductive gel. Surgical tape is used to keep them in position. Tin plate or aluminium electrodes that don't conform to the body are attached to the skin's surface using cotton pads or sponges soaked in tap water. Cotton roll electrodes, clamp electrodes, and sticky electrodes are the intraoral electrodes. Nowadays, adhesive electrodes are the most used kind. Due to their thinness and flexibility, these electrodes can easily acclimate to the oral mucosa.²⁰

Figure no 1: TENS unit A) Adaptor B) TENS unit C) Electrodes D) Lead wire

Procedure: To get rid of any skin oils or other things that can obstruct the flow of electricity, the electrode pad site is gently swabbed with surgical spirit. Before positioning, electrode gel is placed to the electrode pad. The electrode pad is then taped into place to prevent displacement while the patient is advised to open their mouth widely as it is done during therapy. Once the device is turned on, the physician can progressively increase the amplitude dial to the point where the patient feels a noticeable feeling. This amplitude level is kept for the first few seconds to give the patient time to adjust to the novel sensation of electronic anaesthetic. Up until the fasciculation is detected on a neighbouring area, such as the lower lip in the case of a mandibular arch, the amplitude is increased to the next level and the cycle is repeated. Reaching the "minimum therapeutic level," at which the dental procedure can start, is indicated by muscle fasciculation.^{21,22}

Discussion: The primary goal of the paediatric dentist is to gain the child's cooperation during various paediatric procedures in the dental office. The most difficult aspect of the procedure is giving anaesthesia to young individuals. During a paediatric operation, the child's main concern is getting uncomfortable local anaesthetic (LA) injections. A youngster experiences psychological distress at the mere sight of needles and syringes, which

interferes with their ability to control their conduct. Reducing the child's fear of pain during LA injections increases their trust in the dentist, resulting in the child cooperating with the procedure.²³

There are numerous methods available to lessen pain with LA injections. The foundation of transcutaneous electrical nerve stimulation (TENS) is the gate control theory introduced by Melzack and Wall in 1965. The first description of its utilisation in several medicine-related sectors came from Shane and Kessler in 1967. For pain relief during LA injections, transcutaneous electrical nerve stimulation directly stimulates the nerves with electrical impulses of brief duration and small amplitude. During LA injections, transcutaneous electrical nerve stimulation was found to be more comfortable and effective in lowering pain and anxiety.^{12,24}

Analgesic effect of TENS is based on two main theories: Gate control theory of pain and endogenous opioid theory.

Gate control theory; the most widely accepted explanation to describe the mechanism of action of TENS is the gate control theory of pain, which Melzack and Wall developed in 1965. They proposed that the dorsal horn of the spinal cord's substantia gelatinosa serves as a gate control system that modifies afferent patterns from peripheral fibres before they have an impact on the spinal cord's first central transmission [T] cells. Pain is transmitted by tiny, unmyelinated "C" fibres, and their activity retains the gate in a somewhat open posture. To prevent impulses from reaching T cells, activity of big myelinated A fibres closes the gate and pre-synaptically inhibits input from C fibres.¹¹

Endogenous opioid theory, Reynolds (1969) demonstrated in 1969 that electrical stimulation of the periaqueductal grey region of the midbrain causes analgesia comparable to that brought on by morphine. This eventually led to the discovery of a number of morphine-like substances known as endorphins, which exist at different levels of the pain control pathway.²⁵ Therefore, another theory for how TENS works is that it increases the release of endogenous opioids in the spinal cord, which may happen as a result of activating local circuits within the spinal cord or descending pain-inhibitory pathways.²⁶

Choudhari SR et al. (2017) conducted a study on comparison of TENS and 20% benzocaine topical anesthetic gel was done in reducing pain during administration of IANB injection. It was found that TENS can significantly reduce the pain and discomfort when compared to application of 20% benzocaine gel for 2 min.²⁴ In similar study conducted by Siddiqui A et al. (2021) compared efficacy of TENS and lignocaine topical anesthetic gel in reducing pain during administration of IANB injection and found that transcutaneous electronic nerve stimulation can be used as an effective means to reduce the intensity of pain during local anesthetic injection in pediatric dental patients.²⁷

During various dental procedures, electrical stimulation lessens a number of disruptive clinical behaviours, such as weeping and abrupt movement, which aids in the patient's behavioural management.²⁸ A 93% success rate was noted when TENS was used as an analgesic in place of LA during restorative therapies in a research by Bishop.²⁹ From the literature it can be said that EDA is non-invasive, safe and can be used to achieve anesthesia in needle-phobic patients. As compared to local anesthesia there is no postoperative anesthesia after the TENS unit is turned off. Patients are able to self-administer TENS treatment and learn to titrate dosages accordingly to manage their painful condition. This results in positive acceptance by the patients.³⁰

Conclusion: The use of TENS during LA administrations has been found to be much more effective, pleasant, and pain-reducing. Pediatric dentistry has found transcutaneous electrical nerve stimulation to be a safe, dependable, and useful in invasive dental procedures.

Oral Hygiene Practices and Caries Experience among School Leaving Children in Rural Area

Srinivas Ravoori, Suresh Chand Yaddanapalli, Parveen Sultana Shaik, Devaki Talluri, Srinivas Pachava, Nijampatnam P. M. Pavani

Department of Public Health Dentistry, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Background: Dental caries is the most common chronic childhood disease and its treatment is the most prevalent unmet health need among school-leaving children. Caries experience among school leaving age group is important as India is a rapidly growing nation in terms of population as today's children are tomorrow's future citizens of the nation. **Methodology:** To know the oral hygiene practices and caries experience among school-leaving children in a rural area, a cross-sectional study was conducted in the Chebrolu Mandal using a multistage random sampling technique to obtain the required sample size. The data were collected using pretested structured questionnaire followed by oral examination using the decayed, missing, and filled teeth (DMFT) index. The descriptive analysis included mean and standard deviations, Chi-square test, unpaired *t*-test, and one-way analysis of variance. **Results:** Only a few children have a habit of brushing their teeth twice daily 137 (27.6%); rinse their mouth after every meal 116 (23.4%); dispose of toothbrush every 3 months (11.7%); spends <1-min brushing (4.8%); and cleans their tongue using tongue cleaner (25.2%). When DMFT scores were compared to the brushing techniques of the children, significantly higher mean DMFT scores were observed in children who brush once a day (1.49 ± 1.133). **Conclusion:** Caries' experience was more in children who brushed their teeth once a day with horizontal brushing technique and this shows that the study subjects do not follow correct brushing techniques and other oral hygiene practices.

Keywords: Dental caries, DMF index, oral hygiene, tooth brushing

INTRODUCTION

Dental caries is viewed as a most extreme public health problem universally because of its high pervasiveness and critical social effect. The World Health Organization proclaims that 60%–90% of school children worldwide have experienced caries, with the disease being most prevalent in Asian and Latin American countries.^[1] Dental caries is the most common chronic childhood disease and its treatment is the most prevalent unmet health need in children.^[2]

Dental caries affects people of all ages with the highest priority risk group being school-going children. More than 50 million h are lost from schools annually due to oral hygiene-related diseases. Studies have shown that school hours are skipped because of high tooth decay in both primary and permanent dentition. According to the National Oral Health Survey 2002–2003, caries prevalence in India was 63.1% (mean

decayed, missing, and filled teeth [DMFT] 2.3) for 15 years of age group children.^[3]

Dental caries causes pain, discomfort in chewing, food lodgment, headache, restlessness, and sleeplessness and thus influence the esthetic, functional, well-being, and quality of life. It additionally causes foul breath and taste. Further progressed the infection can spread from the tooth to the surrounding soft tissues with resultant complications such as cavernous sinus thrombosis and Ludwig's angina (Cellulitis) which can be life-threatening.^[4]

Children who suffer from poor oral health are 12 times more likely to have more confined activity days including missing schools than those who do not. While there has

been improvement in the oral health of children in the last few decades, tooth decay remains one of the most common childhood diseases, in both industrialized and developing countries. A substantial portion of children in many developing countries are affected by tooth decay and most decay is left untreated due to limited access to oral health services.^[5]

Unfortunately, oral care was more concentrated on the treatment aspect than on preventive care. Oral health is a fundamental part of well-being throughout life, because of the relationship of the oral cavity with the improvement of a personality, discernments, and quality of life. Untreated oral problems among children habitually lead to major general health problems, critical pain, interrupt with eating, and school absence. The earliest sign of a new carious lesion is the appearance of a chalky white spot on the tooth surface, which indicates an area of demineralization of the enamel surface.^[6]

Taking into account that school age is a compelling period during which each child perceives health-related behaviors, convictions, and attitudes and that dental caries is irreversible, endeavors ought to be focused on revealing factors that help in the prevention of dental caries.^[7]

With this background, we have done a study in the Chebrolu Mandal to know the oral hygiene practices and caries experience among school-leaving children in a rural area.

METHODOLOGY

A cross-sectional, multilocality, school children-based study was conducted from December 2019 to January 2020 in Chebrolu Mandal where the list of all the schools, with children of school leaving age, situated in Chebrolu Mandal in Guntur district was obtained from the District Education Officer. A multistage random sampling technique was carried out to obtain the required sample size. For computing sample size, a pilot study was conducted among 20 school children to know the prevalence of dental caries and the feasibility, and validity of the questionnaire. Out of 20 children examined, a prevalence of 80.5% dental caries was observed, while content validity was assessed using the content validity ratio in the target population, and the value was found to be 0.75. The sample size was derived using the formula Z^2PQ/d^2 where Z = standard normal deviate – set at 1.96 at 95% confidence level, P = proportion of the study population ($P = 90.7\%$), $q = 1 - p$, and d = degree of accuracy desired at 0.05; it was determined that 496 school children were included into the study. Ethical clearance was obtained from the institutional ethical committee (37/IRB/SIBAR/2019).

In the first stage, the Mandal was divided into four zones: north, south, east, and west. School children who were present on the day of examination were included in the study. Children with physically or mentally challenged, who were not willing to participate, and were absent on the day of examination were excluded from the study. The structured format consisted of three sections. The first section collected

demographic information of the participants such as age in years, and gender. The second part of the format consisted of questions regarding oral hygiene practices which included the frequency of cleaning and materials used to clean the teeth. The third part consisted of data regarding dental caries experience which was recorded using the DMFT index for permanent dentition. Oral examination was conducted in the school classrooms, under the normal room light with a mouth mirror and CPI probe, and according to the WHO criteria. The collected data were analyzed using the IBM SPSS Statistics for Windows, Version 20.0. IBM Corp, Armonk, New York, USA software package. The descriptive analysis included mean and standard deviations, Chi-square test, unpaired t -test, and one-way analysis of variance. The level of significance was set at $P \leq 0.05$.

RESULTS

A total of 496 children participated in the study, of which 240 (48.4%) are male and 256 (51.6%) are female children with a mean age of 15.23 ± 0.58 years, while 490 (98.8%) of them are using a toothbrush and paste for cleaning their teeth and has adopted horizontal method of brushing (74.2%). Only a few children have a habit of brushing their teeth twice daily 137 (27.6%); rinse their mouth after every meal 116 (23.4%); dispose of toothbrush every 3 months (11.7%); spends <1-min brushing (4.8%); and cleans their tongue using tongue cleaner (25.2%) [Table 1].

The mean DMFT of the study participants was 1.35 ± 1.106 , where males had more mean DMFT score (1.66 ± 1.168) compared to females (1.07 ± 0.964) ($P = 0.001$) while male children reported higher scores of decay component (1.28 ± 1.007), missing component (0.05 ± 0.218), and filled component (0.35 ± 0.655) of the DMFT index [Figure 1].

When DMFT scores were compared to the brushing techniques of the children, significantly higher mean DMFT scores were observed in children who brush once a day (1.49 ± 1.133); who do not rinse their mouth after every meal (1.46 ± 1.018), and in children who spend less than 1 min for brushing (1.79 ± 1.215) [Table 2].

*Statistically significant. Chi-square test. SD: Standard deviation, DMFT: Decayed, missing, and filled teeth

One decayed, two decayed, three decayed, and four decayed teeth were observed to be more in males (40.4%, 23.3%, 10.8%, 2.1%) compared to females (37.9%, 15.6%, 5.1%, 0%) whereas no decayed tooth is observed more in females (41.4%) than males (23.3%) which was statistically significant (0.001) [Table 3].

One decayed, two decayed, three decayed, and four decayed teeth were observed to be more in participants who brushes once a day (40.4%, 21.2%, 8.4%, 1.4%) compared to participants who brushes twice a day (35.8%, 14.6%, 6.6%, 0%) whereas no decayed tooth is observed more in twice a day brushes (43.1%) than once a day brushers (28.7%) which were statistically significant (0.023) [Table 4].

DISCUSSION

Decayed teeth are one of the most common chronic diseases of childhood in the low middle income countries like India where untreated cavities might cause pain and infections that may lead to various problems with eating, speaking, playing, learning, and eventually affects the development of the children.^[8] Children who have poor oral health often miss school and might receive lower grades than the children who do not. Therefore, treating the decay at an early age results in the cessation of further progression of oral diseases thereby lowering the financial burden of dental-care treatment and achieving a better quality of life.^[9]

In the present study, 240 (48.4%) were male and 256 (51.6%) were female children showing a female preponderance which was, in contrast, to the study done by Singh and Sethi^[10] where male children are more than female children. Four hundred and ninety (98.8%) children use a toothbrush and paste which was similar to the study conducted by Bhagat *et al.*^[11] while 2 (0.4%) of them use the finger with tooth powder as oral hygiene practice.

In this study, the overall mean DMFT of school children was 1.35 ± 1.106, and boy's mean DMFT (1.66 ± 1.168) was slightly higher than girls (1.07 ± 0.964), which was, in contrast, to a study done by Pai *et al.*^[12] and Aparna *et al.*^[13] and Al-Rafee *et al.*^[14] where the mean DMFT of study subjects was higher when compared to the present study, whereas the mean DMFT for the present study was higher when compared with the studies done by Goel *et al.*^[15] and Brighton Mafuvadze *et al.*,^[16] Okeigbemen^[17] and Bhagat *et al.*^[11] In the current study, the mean DMFT for male children was 1.28 ± 1.007, 0.05 ± 0.218, 0.35 ± 0.655, respectively, and for females was 0.84 ± 0.867, 0.02 ± 0.176, 0.20 ± 0.514, respectively, which was higher in males than in females, might be due to the reason that the females are concerned with aesthetics and also could be because they maintain their oral hygiene better than males, which was similar to the study conducted by Aparna *et al.*^[13] and it was in contrast to the studies done by Brighton Mafuvadze *et al.*,^[16] Khalid *et al.*^[18] and Arora *et al.*^[19] In the present study, the mean DMFT is less when compared with the retrospective analysis done by Kundu *et al.*^[20]

Table 3: Frequency of gender wise distribution of the decayed tooth

Gender	No decay, n (%)	One decayed tooth, n (%)	Two decayed tooth, n (%)	Three decayed tooth, n (%)	Four decayed tooth, n (%)	P
Male	56 (23.3)	97 (40.4)	56 (23.3)	26 (10.8)	5 (2.1)	0.001*
Female	106 (41.4)	97 (37.9)	40 (15.6)	13 (5.1)	0	

*Statistically significant. Chi-square test

Table 4: Comparison of frequency of tooth brushing with the number of decayed teeth

Frequency of brushing	No decay	One decayed tooth	Two decayed tooth	Three decayed tooth	Four decayed tooth	P
Once	103 (28.7)	145 (40.4)	76 (21.2)	30 (8.4)	5 (1.4)	0.023*
Twice	59 (43.1)	49 (35.8)	20 (14.6)	9 (6.6)	0	

*Statistically significant. Chi-square test

In this study, dental caries was recorded higher in males than females; this might be because females are more concerned with esthetics so they got them treated with tooth-colored restorations. Because girls are fond of esthetics, as a result, girls might brush and floss their teeth more thoroughly every day during this period to avoid gum diseases and has better oral health than their counterparts.^[21]

In the present study, children who brushed twice daily showed 43.1% caries free when compared to children who brushed once daily. Brushing twice results in good oral hygiene, whereas the lower rates in caries-free study subjects might be due to improper brushing techniques and poor oral hygiene practices. Tooth brushing is regarded as an important vehicle for the application of anti-caries agents, such as fluorides into our system. Most patients still cannot accomplish adequate plaque removal by performing oral cleanliness procedures at home. As a result, most dentists recommend brushing teeth twice a day to improve oral hygiene through plaque control. Brushing twice also eliminates food impaction while shortening the impact of sucrose by cleaning teeth after meals seems to be recommendable.^[22]

Limitations

Cross-sectional studies are observational studies that look at data from a group of individuals at one point in time. They are widely used to assess the prevalence of health outcomes, comprehend health determinants, and identify population characteristics. Finally, the detection of dental caries in children was performed without radiographs.

Recommendations

Hierarchical studies have to be done to find out oral hygiene practices and caries experience among school leaving children in rural areas as most of the population in India lives in rural parts than in the urban counterparts where there was fewer establishments of oral health services.

CONCLUSION

Although the overall caries experience in the present study was less and a very less number of children had a habit of

brushing twice daily, caries experience was more in children who brushed their teeth once a day, majority of the children adopted to horizontal brushing technique and this shows that the study subjects do not follow correct brushing techniques and other oral hygiene practices. There is a need to conduct oral health education programs on correct brushing techniques and other oral hygiene aids.

Background. Oral and oropharyngeal cancer is a debilitating disease with high morbidity and mortality. Depending on the site and extent of the involvement of the cancer and the type of treatment modality, these patients can develop pain, trismus, xerostomia, dysphagia, and taste disturbances, compromising them socially and nutritionally. The aim of the study was to evaluate malnutrition and quality of life in patients treated for oral and oropharyngeal cancer. **Methodology.** A cross-sectional study was conducted which included 97 patients treated for oral and oropharyngeal cancer. The quality of life of the selected patients was assessed by using a validated European Organization for the Research and Treatment of Cancer's Quality of Life Questionnaire, Head and Neck and Mandibular Function Impairment Questionnaire. Pre- and posttreatment weight of the patients were assessed, and weight loss of $\geq 10\%$ of pretreatment weight was considered as malnutrition. The chi-square test was used to correlate the symptoms with the quality of life. A paired *t* test was used to assess the differences in weight before and after treatment, and a *p* value of < 0.005 was considered as significant. **Results.** The most commonly reported symptoms were xerostomia (93.81%), pain (81.44%), and dysphagia (76.3%). A total of 40.2% of the individuals in the study had malnutrition. Malnutrition was comparatively lower in the group who had nutritional supplements. **Conclusion.** The quality of life in patients treated for oral and oropharyngeal cancer deteriorates immediately after the treatment; however, it significantly improves over time.

1. Introduction

In a developing country like India, head and neck cancer is quite common and is ranked as the tenth most common cancer by the International Agency for Research on Cancer [1]. In 2018, global incidence and mortality related to oral and oropharyngeal cancer were estimated to be 447,751 and 228,389, respectively, and in India, incidence and mortality rates were recorded to be 137,895 and 87,569, respectively [2]. The number of oral and oropharyngeal cancer survivors has increased in the recent decade owing to superior diagnostic techniques and advanced treatment modalities [3–5]. Although the number of deaths has decreased, the treatment of oral and oropharyngeal cancer leaves patients compromised physically and mentally [3, 6]. Various

treatment modalities of oral and oropharyngeal cancer include surgery, chemotherapy, radiotherapy (RT), or a combination of them [7, 8]. Depending on the site and extent of the involvement of cancer and the type of treatment modality, these patients develop pain, trismus, xerostomia, dysphagia, and taste disturbances compromising them socially and nutritionally. The present study was undertaken with an aim to assess malnutrition and the quality of life (QOL) in patients treated for oral and oropharyngeal cancer.

2. Materials and Methods

Sample size calculation: Based on the article by Kamstra et al., [9], the correlation coefficient derived/reported is 0.67. With an alpha error of 0.1% and a power of 99.9%, the *Z*

values of the given alpha and beta values are 3.29 and 4.26. With the correlation coefficient and using the above-mentioned formula, the required sample size was 87 in number. A prospective study was conducted on 97 patients treated for oral and oropharyngeal cancer after obtaining clearance from the Institutional Ethical Committee (Ref Protocol No. 15121). Inclusion and exclusion criteria for the study are given in Table 1.

Demographic data, pretreatment weight, details including the site, extent, and staging of the cancer, and treatment details including the mode of treatment and duration were retrieved from hospital records. The study population was divided into two groups, namely, the 3 months group and 6 months group, i.e., individuals who came before 3 months and at 6 months for follow-up after treatment. On the day of the study, informed consent was obtained from the patients and they were then clinically evaluated. As part of the study, body weight was assessed and the patient's oral cavity was thoroughly examined to evaluate their mouth opening, dentition, oral hygiene, and for the presence of any mucosal abnormalities. Patients were then asked about the symptoms related to their treatment and were asked to grade their symptoms by using the European Organization for the Research and Treatment of Cancer's Quality of Life Questionnaire and the Head and Neck35 (EORTC QOL-H&N35) and Mandibular Function Impairment Questionnaire (MFIQ). These questionnaires were modified in few areas to suit the Indian population and validated by our resident dietician and oncologist. The quality of life was assessed, and changes in the body weight were correlated with the scores of the questionnaire. All data were coded and transferred to an Excel spreadsheet (Microsoft Corp., Redmond, WA, USA), and a descriptive statistical analysis was performed using SPSS version 20.0 (SPSS Inc., Chicago, IL, USA) with a confidence limit of 80%. Items from both the questionnaires were grouped according to symptoms such as swallowing problems, chewing disabilities, dry mouth, sensory impairment, impaired social activities, and psychological problems. The range of score for each symptom was calculated by adding all the lower and upper limits of questions in that group from both the questionnaires. The range of score obtained for each symptom was divided into 3 groups, namely, mild, moderate, and severe, by extracting an average of the scores of the 2 questionnaires, and the patients with moderate and severe scores were considered to have a significant problem. An example for the averaging of scores is as follows: To address the chewing problem, we have question numbers 4, 5, 6, 10, 12, 13, 14, and 15 from the validated MFIQ and question number 15 from the validated EORTC. Hence, for chewing problems, the minimum and maximum score obtained were 9 and 36, respectively. This range of score is divided into three categories: $9 \leq 18$ which denotes patients having mild problems, $19 \leq 27$ indicating moderate problems, and $28 \leq 36$ denoting severe problems. The categorization of the questions addressing each problem is given in Table 2. The scores and grading for each symptom are given in the Table 3. The chi-square test was used to correlate the symptoms with the quality of life. The paired *t* test was used to assess the

TABLE 1: Inclusion and exclusion criteria of the study.

Inclusion criteria
(i) Patients aged above 18 years who were treated for oral and oropharyngeal cancer
Exclusion criteria
(i) Patients with metastatic disease, i.e., stage IV C
(ii) Patients treated with cancer below the level of the hypopharynx
(iii) Patients with poor performance state, not fit to receive any radical treatment
(iv) Patients not fit for concurrent chemotherapy
(v) Patients not willing to provide the consent for study
(vi) Patients who did not complete the course of treatment

differences in weight before and after treatment, and a *p* value of <0.005 was considered as significant.

3. Results

Among the 97 patients treated for oral and oropharyngeal cancer, 74.2% of the patients were male and 25.8% were females. The mean age of the study population was 55 (SD \pm 10.6) years. 78% of the patients had consumed tobacco either in the smoke or smokeless form, and 60% had consumed alcohol on a regular basis. The site of involvement, staging, and treatment details are summarized in Table 4.

The most commonly reported symptoms were xerostomia (93.81%), pain (81.44%), and dysphagia (76.3%). Chewing problems and psychological scores had significantly reduced in the 6 months group when compared to the 3 months group. The comparison of scores for quality of life in the 3 months and 6 months group is shown in Figure 1.

Comparison of weight changes between the two groups showed statistically nonsignificant results with a *t* value of 1.73 but was statistically nonsignificant with a *p* value of 0.098. Malnutrition between the 2 groups was compared, and it was noted that the prevalence of malnutrition was significantly higher (56.4%) in the 3 months group (*p* value 0.04). Only sensory difficulty for taste sensation was significantly associated with malnutrition (*p* value 0.029). The results for association between other symptoms with malnutrition are shown in Table 5.

The results from the chi-square test showed that malnutrition was significantly lower in the group which had nutritional supplements (*p* value 0.033). Chewing problems, dysphagia, and dry mouth (sticky saliva) were significantly observed to be higher among individuals treated with surgery alone, and trismus was significantly higher in patients who were treated with a combination of surgery and RT. The association between the oral symptoms, psychological burden, and impaired social activities with various modes of treatment is given in Table 6.

4. Discussion

Cancers affecting the oral and oropharyngeal region and their treatment modalities adversely affect the patients' emotional, physical, and functional well-being. These experiences can deeply scar the patients' lives leading to a

dramatic decrease in their QOL and can indirectly cause malnutrition. The QOL assessment is an important tool measuring the outcomes of cancer treatment and has been evaluated in this study.

In our study population, the male-to-female ratio was 2.88:1 which is similar to the results of Nagy et al. [1] (2:1), Gritz et al. [10] (2.5:1), and Hassanein et al. [11] (2.3:1). The mean age of the study group was 55 years which is consistent with the results of Nagy et al. [1] (53.8 years), Gritz et al. [10] (58.4 years), and Hassanein et al. [11] (58 years). The most common site of tumor in our study was the tongue (35%)

FIGURE 1: Representing comparison of scores between the 3 months and 6 months group.

followed by the floor of the mouth (18.6%), oropharynx (12.4%), maxilla (12.4%), and buccal mucosa (10.3%). Our results were similar to studies conducted by Rinkel et al. [12] who stated that the common sites were the tongue (38%), followed by the floor of the mouth (10%).

The most common treatment modality in the present study was the combination of surgery with RT, followed by the combination of surgery, RT, and chemotherapy (CT). This can be explained by the fact that most of the cancers in our study were in stage II and stage III which usually required combined treatment modalities. Combination of surgery with RT was the common mode of treatment in the studies conducted by Rinkel et al. [12] (50%), Kamstara et al. [9] (51.25%), and Nazar et al. [13] (47.2%). In the study conducted by Scharloo et al. [14], the results showed that RT was the commonly employed treatment modality and accounted for 40.7% of the cases. Thomas et al. [15] found that 88.3% of the patients had undergone primary or adjuvant RT. In the investigation carried out by Vartanian et al. [16] on 301 patients, it was found that 52.5% of the patients were treated only by surgery, 11.3% had undergone only RT,

and 32.6% were treated with a combination of surgery and RT.

In the present study, the most commonly reported symptoms were xerostomia (93.81%) followed by pain (81.44%) and dysphagia (76.28%). These findings can be explained by the fact that most of the participants were treated by RT. Xerostomia chiefly occurs due to the severe damage and fibrosis of salivary glands caused by RT. These findings were similar to the results of the study conducted by Kamstara et al. [9] who observed that xerostomia was the most common symptom among patients treated for oral and oropharyngeal carcinoma and the other most commonly reported symptoms were trismus and dysphagia. Rathod et al. [17] in their study noticed that xerostomia was the most common symptom associated with the treatment of HNC. The study also revealed that dysphagia and altered taste sensations in oral cancer patients worsened after treatment. A study conducted by De Graeff et al. [18] revealed that the common symptoms associated with treatment of oral and oropharyngeal cancer were pain, difficulty in eating and speech, and sensory impairment. Pain was the second most commonly reported symptom in our study (81.44%). Most of the studies in the literature have suggested pain as the worst symptom experienced as a consequence of cancer therapy [19]. The experience of pain after surgery is described as a nociceptive pain, lasting for a couple of months with moderate improvement over time [20, 21]. Surgical management can also cause tissue and nerve damage resulting in chronic pain syndromes. Terrel et al. [22] in their study among patients treated by mandibular bone resection found that hyperalgesia and allodynia was experienced by approximately 50% and 90% of the patients, respectively. Pain can also be because of the mucositis since most of the patients had undergone the combination of surgery and RT. The systematic review by Trotti et al. [23] stated that the

incidence of oral mucositis in patients treated with RT and chemoradiation was very high accounting for 80% of the patients.

In the present study, the scores of various symptoms were lower in the 6 months group when compared to scores of individuals in the 3 months group. These findings suggested that the severity of the symptoms decreased as the duration of treatment increased. The scores of chewing disabilities, trismus, dysphagia, pain, taste disturbances, and psychological scores were comparatively lower among individuals who came for follow-up at 6 month interval. However, only the scores of chewing disabilities and psychological burden were significantly reduced in the 6 months group when compared with the 3 months group. This can be attributed to the prophylactic extraction of teeth and the consequent inadequate healing of the surgical site as a part of the treatment protocol or even a lack of proper prosthetic wear at 3 months interval during treatment follow-up. The improvement at 6 months may be due to the healing of the surgical site in such cases. Adverse effects of treatment such as extraoral surgical scars, pigmented skin, and alopecia which can significantly impact the psychological well-being of individuals are severe immediately after treatment but improve subsequently over time. These treatments also contributed to inability in movement of the tongue resulting in difficulty of speech. All these factors inhibit them from routine activities such as social speaking and social eating and eventually affect them psychologically in due course of the treatment. The scores for sensory difficulties, xerostomia, and impaired social activities are higher in 6 months group when compared with the 3 months group; however, the difference was not statistically significant.

Biazevic et al. [24] recorded the immediate effects of tumor resection in oral and oropharyngeal cancer on the

health-related QOL and found reduction in overall rating indicating the improvement of the QOL after 6 months of treatment. It was observed that the commonly impaired functions were chewing difficulties, taste disturbances, pain, and problems associated with swallowing and speech. In the current study, comparison of the scores between 3 months and 6 months showed significantly high scores in chewing problems and psychological burden in the 3-month interval group. Jaw movements for opening chewing and swallowing are correlated with mobility of the tongue and the mandible. Most of our patients were treated for cancer of the tongue and floor of the mouth which have significant effects on chewing and swallowing functions. These are also significantly impaired immediately after the treatment, but improve after a duration of 6 months, which explains the reduction of their scores.

Shepherd et al. [25] conducted a study on oral cancer patients with an aim to examine the impact of surgical, RT, and combination treatment on QOL. In this study, it was found that function reduced immediately after treatment and most functions improved to near baseline levels by 3 months after treatment. Rathod et al. [17] evaluated the outcomes of treatment in HNC patients and noticed that there was a substantial deterioration in the QOL (trismus, xerostomia, pain, and senses) scores 3 months after treatment although the improvement was noted in all the scores by 6 months' time. These findings were very similar to the findings of our present study. Agarwal et al. [26] in a prospective study evaluated changes in the QOL 6 months after the surgical treatment of carcinoma of the tongue and found that there was a significant decrease in scores of the appearance of the patient, dysphagia, chewing, speech, taste, and xerostomia indicating an improvement of the QOL.

Prevalence of malnutrition (weight loss of $\geq 10\%$) in our study was 40.2%, among which 56.4% were in the 3 months group and 43.6% in the 6 months group. Taste disturbances were significantly associated with malnutrition. Altered taste sensation is very distressing for the patients and is associated with decreased appetite and confusion between bitter and sour taste and the inability to discriminate among various tastes. The results of our study were similar to a few other studies in the past. McLaughlin [27] had found that dysgeusia has shown a statistically significant association with malnutrition. Suzuki et al. [28] had revealed that appetite is frequently affected by altered taste sensation along with xerostomia and oral mucositis. Ogama and Suzuki, [29] concluded that patients who were exposed to a cumulative dose of 50 Gy had taste disturbances which severely affected their appetite. However, studies conducted by Jager-Witenaar et al. [30] and Gellrich et al. [31] showed that dysphagia and chewing problems were mainly associated with malnutrition. Kubrak et al. [32] has suggested that malnutrition may be due to dysphagia and mouth sores caused by the treatment of oral and oropharyngeal cancer.

Our research revealed that malnutrition was absent in a significant number of patients (72.5%) who were on nutritional supplements. Ravasco et al. [33] in a prospective study on HNC patients stated that weight loss is more prevalent in patients who were not receiving dietary

counselling when compared to patients who received dietary counselling. van den Berg et al. [34] stated that nutritional interventions during treatment had a positive influence on the outcomes of treatment and resulted in considerably lower malnutrition status in patients treated for oral and oropharyngeal cancer.

5. Conclusions

In the present prospective study, we observed that the QOL in patients treated for oral and oropharyngeal cancer deteriorates immediately after treatment but significantly improves over time. Our study also highlights the importance of nutritional supplements, their positive influence on the outcomes of treatment, and their beneficial effects on patients with malnutrition.

Mesoporous
Carbonated hydroxyapatite

ABSTRACT

Utilizing eggshells to synthesize a value added product like nanocrystalline hydroxyapatite (HA) has received a lot of attention from researchers since they are composed of CaCO₃ with biologically essential trace elements such as Mg, Si, etc. Different biomedical applications need HA with appropriate nanoscale characteristics like crystallinity, particle size, morphology, surface area, mesoporous nature, etc. The same can be achieved by tuning the reaction parameters, choosing a suitable mode of preparation and utilizing organic modifiers. Here, we report the rapid synthesis of eggshell derived HA in the presence different organic modifiers using a custom built microwave reactor employing the previously optimized parameters. The synthesis process is relatively rapid and gets completed in 5 min. The absence of an organic modifier yielded inhomogeneous size nanorods in the range of 40 – 600 nm. Ethylenediaminetetraacetic acid (EDTA) assisted synthesis resulted in a flower like 1.67 ± 0.12 μm sized HA. Whereas polyethylene glycol 6000 (PEG) and cetyltrimethylammonium bromide (CTAB) assisted synthesis produced aggregated nanorods of length 31 ± 8 and 68 ± 20 nm, respectively. While the synthesis with trisodium citrate dihydrate (TSC) resulted in needles of HA with typical length of 32 ± 8 nm. Presence of Na, Mg and Si trace elements are confirmed from the composition analysis. All the samples are found to be mesoporous in nature. The *in vitro* cell culture experiment carried out using fibroblast NIH 3T3 cell line clearly revealed equal or higher cell viability for the samples synthesized in presence of organic modifiers as compared to sample produced without organic modifier. Thus, from the present study we find that the synthesis of eggshell derived HA using different organic modifiers via a custom built microwave reactor can be a potential approach for the rapid preparation of precursor materials with suitable nanoscale characteristics for developing bone fillers, drug/protein delivery carriers, tissue engineering scaffolds, etc.

1. Introduction

Hydroxyapatite [HA, Ca₁₀(PO₄)₆(OH)₂] is the dominant mineral phase in the human skeletal system [1,2]. Synthetic HA has been widely used in bone tissue engineering and other biomedical applications in dentistry and orthopaedics owing to its compositional and structural similarity with the mineral phase of bone and teeth [3,4], consequently its excellent bioactive and cytocompatible nature [5]. In addition, the usage of HA is not only limited to the biomedical field, but also used as an adsorbent for organic dyes and heavy metal ions, catalyst, electret

and proton conductor [6–8]. Current scenario is the development of HA based materials with enhanced properties through nanotechnology by utilizing novel physical/chemical processes [6,9]. Nanoscale characteristics of HA should be optimized to achieve better performance for different biomedical applications [10]. Particularly, the physicochemical and biological properties of mesoporous HA nanostructure is different from bulk materials [9,11]. Moreover, factors such as crystallinity, particle size, morphology and surface area of mesoporous HA nanostructures play a vital role in biomedical applications [12]. Hence, significant efforts are being made to control the size and shape of HA

nanoparticles.

It was found that the preparation method dramatically influences the characteristics of the HA produced. The reaction parameters such as temperature, pH, ageing time, etc. are also important to synthesize HA with superior nanoscale characteristics [13]. Moreover, different organic modifiers and surfactants were also effectively used to control the characteristics of nano HA since calcium and phosphate ions can

easily interact with organic species during the synthesis [14]. Several methods such as chemical precipitation [15], sol-gel [16], micro-emulsion [17], hydrothermal [11], electrochemical [18], microwave [19] and solid state method [20] were reported for the synthesis of nano HA. Among the different synthesis methods, the microwave technique is an efficient and straightforward method to prepare HA nanoparticles rapidly. In the past few decades, many research papers have been published on the synthesis of HA using the conventional domestic microwave oven [19].

Several researchers have utilized various biogenic sources such as corals, eggshells, fish scales, seashells, animal bones, etc., as a calcium source to synthesize nanocrystalline HA [15]. Among them, eggshells are a highly preferred calcium source since they are mainly composed of 94% calcium carbonate (CaCO_3) with trace elements such as magnesium (Mg), silica (Si), etc., [21]. Annually worldwide large quantities of eggshells are discarded as landfills from restaurants, hatcheries, etc., [22]. Moreover, when compared to HA derived from commercial reagents, eggshell derived HA exhibited superior bioactivity, excellent osteoconductivity, osteoinductivity and cell proliferation and is often attributed to the presence of trace elements that originated from the eggshell source [23]. Egg white and eggshell based hydrogel composite scaffold fabricated by Huang et al. exhibited better bioactivity [24]. Bone cement and 3D scaffold prepared from eggshell derived calcium phosphates were reported to be suitable for hard tissue regeneration, as it has a good cement setting behaviour, compressive strength, biocompatibility and better osteogenic differentiation as compared to synthetic bone cement/scaffold [25,26]. Also, eggshell derived nano HA reinforced with the polymer to fabricate composite membrane or scaffolds revealed enhanced thermal, mechanical and biological properties compared to pure polymer membrane/scaffold [27-29]. Protein delivery, drug delivery and waste water remediation have also been studied using eggshell derived HA [7,30,31].

Although several reports are available on the synthesis of nano HA from eggshell through different techniques, microwave assisted chemical precipitation is highly preferred by several researchers due to its advantages like simplicity, economical, rapid process, reproducibility, high yield, etc., [19]. Also, recent research suggested that microwave technique directly results in mesoporous HA nanostructures even without employing hard templates or surfactants [32,33]. Nanoscale HA with mesoporous characteristics have received significant attention in developing drug/protein carriers, implants and tissue engineering scaffolds. Even though mesoporous HA can be obtained via microwave technique, we can control the size, morphology and mesoporous characteristics of HA using different organic reactive molecules. Recently, we reported the impact of various reaction parameters for HA synthesis from eggshell waste using lab scale and a custom built pilot scale microwave reactor made using four magnetrons (1.1 kW per magnetron) [34]. The custom built pilot scale microwave reactor significantly reduced the microwave irradiation time as compared to the domestic microwave oven used as a lab scale reactor. The objective of the present work is to study the formation of eggshell derived HA using the above mentioned custom built pilot scale microwave reactor in the presence of reactive organic compounds such as EDTA, PEG, TSC and CTAB employing the necessary parameters optimized in the previous work.

2. Experimental

All the chemicals, namely nitric acid (HNO_3), disodium hydrogen phosphate (Na_2HPO_4), sodium hydroxide (NaOH), ethylenediaminetetraacetic acid ($\text{C}_{10}\text{H}_{16}\text{N}_2\text{O}_8$), polyethylene glycol 6000 ($\text{H}(\text{OCH}_2\text{CH}_2)_n\text{OH}$), trisodium citrate dihydrate ($\text{C}_6\text{H}_9\text{Na}_3\text{O}_9$) and cetyltrimethylammonium bromide ($\text{C}_{19}\text{H}_{42}\text{BrN}$) were analytical reagent grade acquired from Merck, India. All reagents were used without further purification and double distilled water was employed as the solvent. Broiler eggshells were utilized as the calcium source in the present study due to its abundant availability in India.

Fig. 3. HRTEM images and SAED pattern of EHA and EHA-1. Inset in Fig. 3(c) is the SEM image of EHA-1.

2.1. Custom built pilot scale microwave reactor

The pilot scale microwave reactor used in this study was developed by modifying conventional microwave furnace (supplied by VB ceramic consultants, Chennai, India). The reaction vessel used for the reactor replaced the susceptor of the microwave furnace. The reactions were conducted in water as the dielectric medium. The reaction vessel was designed in such a way with the lid having the provisions for inlet and outlets. A suction pump is connected to the reaction vessel for releasing the pressure. There are four magnetrons (1.1 kW/magnetron, 2.45 GHz) of which two operate at a time, one on both side to allow homogeneous radiation inside the reactor. Hence, microwave power during the operation is 2.2 kW. After completing the reaction, the instrument is manually switched off as the sensing unit of microwave furnace that allows automatic power cut-off cannot be used when the instrument is operating in reactor mode.

Eggshells were collected, cleaned manually and then placed in a furnace at 900 °C for 1 h. At this temperature, eggshells transform into calcium oxide (CaO) by evolving carbon dioxide (CO₂) according to the following equation (1).

The eggshell derived CaO (0.1 M) was dissolved in nitric acid (0.2 M) to form calcium nitrate solution (eqn. (2))

0.06 M disodium hydrogen phosphate solution was prepared by dissolving an appropriate amount of Na₂HPO₄ in double distilled water. Obtained calcium nitrate solution was stirred vigorously at room temperature to which Na₂HPO₄ solution was added dropwise while maintaining the pH of the reaction mixture above 10 using NaOH and was stirred for 30 min at room temperature. The expected chemical reaction is given in equation (3),

The obtained reaction mixture (100 ml) was transferred into the microwave reactor chamber followed by microwave irradiation at 2.2 kW for 5 min. The resulting white precipitate acquired was centrifuged (6000 rpm) and washed 6 times with double distilled water to remove the by-products, followed by drying at 110 °C for 5 h in a hot air oven. Finally, dried cakes were crushed using mortar and pestle to get white powder which is named as EHA. Experiments were also carried out in presence of EDTA (0.2 M) [34], PEG (1 wt.%) [35], TSC (0.0333 M) [36] and CTAB (0.06 M) [37] in which the former three organic modifiers were added along with the calcium reagent while the latter one was mixed with phosphate reagent. The individual organic modifier concentration mentioned above was chosen based on the optimized concentration available in the literature. The samples prepared using EDTA, PEG, TSC and CTAB were named EHA-1, EHA-2, EHA-3 and EHA-4 respectively.

Fig. 4. (a, b) HRTEM images (c) SAED pattern of EHA-2 sample

2.2. Characterization

Phase purity, crystalline nature and lattice parameters of the synthesized samples were analysed by powder X-ray diffraction (XRD) technique (Rigaku MiniFlex-II) using monochromatic Cu- α radiation (1.5406 Å). The powder XRD patterns were recorded in the range between $20^\circ \leq 2\theta \leq 60^\circ$ with a scan speed of $10^\circ/\text{minute}$ and step size of 0.02° . In addition, the full width at half maximum (FWHM) was calculated from the XRD pattern to measure the average crystallite size by the Scherrer method [38].

The functional groups present in the prepared samples were examined using Fourier transform infrared spectroscopy (FTIR). Powder samples were ground with KBr and pressed into a disc using a pelletizer. The FTIR spectra were recorded from 4000 to 400 cm^{-1} using a Perkin Elmer RX1. Particle size, morphology and crystalline nature of the prepared samples were analysed using high resolution transmission electron microscopy (HRTEM- JEOL/JEM 2100) and selected area electron diffraction (SAED). For HRTEM analysis, small amount of sample was dispersed in ethanol under sonication for 30 min and $1\ \mu\text{l}$ of the dispersed sample was placed on the carbon coated copper grid. The elemental composition of the samples was analysed using energy dispersive X-ray analyser (EDAX) by INCA, Oxford instruments. Scanning electron microscopy (SEM, Carl Zeiss - EVO 18) was used to analyse the surface morphology of the prepared samples.

The pore size, pore volume and surface area of the samples were determined using the N_2 adsorption-desorption isotherm method

(Micromeritics ASAP 2020). In addition, thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) of synthesized products was carried out from 34 to 1200°C with heating rate of $10^\circ\text{C}/\text{minute}$ using Jupiter (NETZSCH STA F3) instrument.

2.3. Cytocompatibility assay

The cytocompatibility of samples was tested with fibroblast NIH 3T3 cell lines (purchased from National Centre for Cell Science (NCCS), Pune, India) by MTT assay. The fibroblast NIH 3T3 cells were cultured with 10% of fetal bovine serum (FBS) and 1% of penicillin-streptomycin followed by incubation at 37°C with the humidified atmosphere in 5% of CO_2 . The cultured fibroblast cells were sowed at a density of 1×10^5 cells/ml in 96 well tissue culture plate and incubated at standard culture settings (37°C , 5% of CO_2 and 95% air) for 24 h. After incubation, synthesized powder samples were added into tissue culture plate at various concentrations such as 50, 100, 250 and $500\ \mu\text{g}/\text{ml}$ and then incubated at 37°C for 24 h in CO_2 incubator. Thereafter, $15\ \mu\text{l}$ of MTT and phosphate buffered saline (PBS) was added to 96 well plate and then incubated at 37°C for 4 h in a CO_2 incubator. After this, the supernatant of MTT solutions was discarded and the obtained formazan crystals were dissolved in $100\ \mu\text{l}$ of dimethyl sulfoxide (DMSO) and the optical density (OD) was measured at $570\ \text{nm}$ using a microplate reader. The percentage of viable cells was calculated from the following equation (4)

$$\text{Percentage of cell viability} = \left(\frac{OD_{\text{sample}}}{OD_{\text{control}}} \right) \times 100 \quad (4)$$

Dr. L. KRISHNA PRASAD

Fig. 5. HRTEM images (a & c) SAED pattern (b & d) of EHA-3 and EHA-4 sample

Table 2

Elemental composition of the prepared samples.

Sample code	Elements (at.%)					Ca/P
	Ca	P	Na	Mg	Si	
EHA	11.50	07.64	0.41	0.23	0.16	1.51
EHA-1	10.61	07.48	0.74	0.18	0.18	1.42
EHA-2	15.03	10.29	2.81	0.57	0.27	1.46
EHA-3	12.47	08.37	0.23	0.03	0.18	1.49
EHA-4	06.47	04.72	0.22	0.05	0.13	1.37

where, OD_{sample} is the optical density of cells with powder sample and OD_{control} is the optical density of cells without sample.

2.4. In vitro cell attachment study

300 mg of prepared powder sample was made into a disc of about 13 mm diameter and 1 mm height using pelletizer by applying pressure at 20 MPa. The prepared disc samples were transferred to 6 well tissue culture plate. Fibroblast NIH 3T3 cells were cultured in 96 well plate at a density of 1×10^5 cells per well in Dulbecco's modified eagle medium (10% of FBS and 1% of penicillin-streptomycin) under incubation at 37 °C for 24 h in CO₂ incubator. 200 μ l of the above cultured cells were seeded on the surface of the disc and incubated at 37 °C for 24 h in a CO₂ incubator. Then, the culture media was removed and the samples were

washed with PBS and the discs were fixed with 4% of glutaraldehyde solution for 30 min followed by slow dehydration in ethanol of concentration 70%, 80%, 90% and 100% and dried at room temperature. Then, the dried samples were sputter coated with gold for 10 min to observe cell attachment on the surface using field emission scanning electron microscopy (FESEM, JEOL JSM-6390L).

3. Results and discussion

3.1. XRD

Fig. 1 shows the powder XRD patterns of samples prepared without and with the organic modifier. From the obtained XRD patterns we have seen that all five samples exhibited the characteristic diffraction peaks of HA (JCPDS file no: 09-0432 with hexagonal structure) without any other calcium phosphate phases. Pristine EHA (sample prepared without organic modifier) sample exhibit resolved peaks in between 30 and 35°. However, a significant decrease in the intensity of the diffraction peaks was observed for samples prepared with organic modifier EHA-1, EHA-2, EHA-3 and EHA-4. Moreover, the broadness of the diffraction peaks was found to increase for EHA-1, EHA-2, EHA-3 and EHA-4. These results clearly indicate that the presence of an organic modifier during the sample preparation plays a crucial role in modulating crystallization and control the growth of HA under microwave irradiation. The calculated average crystallite size and crystallinity of EHA, EHA-1, EHA-2, EHA-3 and EHA-4 are given in Table 1. It is interesting to note that PEG, TSC

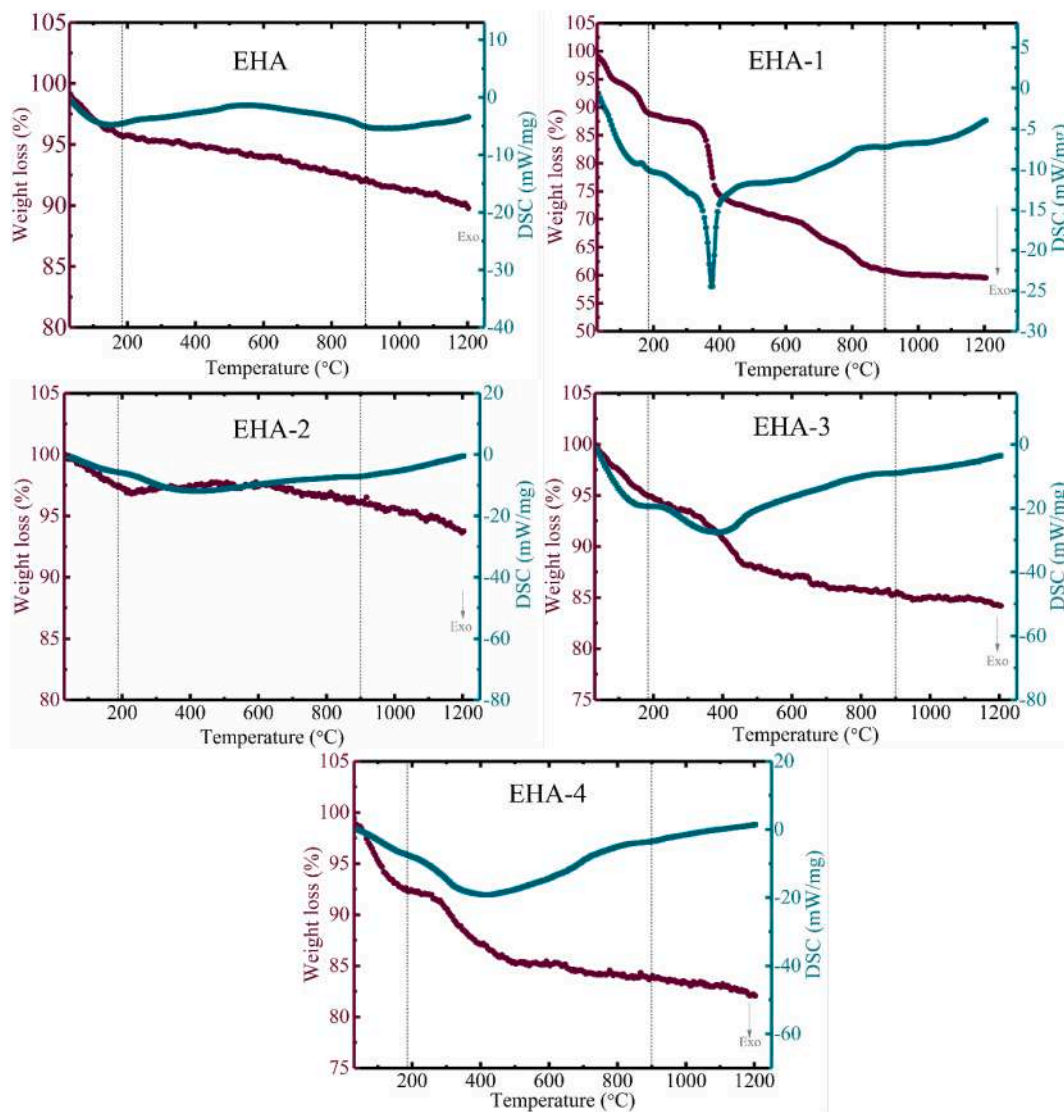

Fig. 6. TGA/DSC curves of the prepared samples

Table 3

Weight loss percentage of the prepared samples.

Sample code	Weight loss (%)			Total weight loss (%) (34–1200 °C)
	Step-I (34–180 °C)	Step-II (180–900 °C)	Step-III (900–1200 °C)	
EHA	4.26	3.58	2.38	10.22
EHA-1	11.03	28.07	1.36	40.46
EHA-2	2.51	1.33	2.41	6.25
EHA-3	5.04	9.42	1.36	15.82
EHA-4	7.43	8.56	1.93	17.92

and CTAB highly inhibited the crystallization of HA when compared with EDTA. Lattice parameters and lattice distortion of prepared samples were calculated and listed in Table 1. Significant difference in the crystallite size and crystallinity were found in between the prepared samples, which also confirm that organic modifiers can play a vital role in crystallization of HA by making interaction with calcium/phosphate precursor [13].

3.2. FTIR

FTIR spectra of samples prepared without and with organic modifiers

are shown in Fig. 2. In the FTIR spectra the doublet peak observed at 604 and 566 cm^{-1} corresponds to the characteristic bending mode of phosphate (PO_4^{3-}) group of HA. Also, other phosphate peaks of symmetric and antisymmetric stretching vibrations appeared at 962 and 1030–1120 cm^{-1} respectively. The small peak detected for all the samples at 475 cm^{-1} is assigned to the bending mode of PO_4^{3-} group. The peaks that are present at 631 and 3572 cm^{-1} are ascribed to the characteristic OH^- group of HA and they are very sensitive to the crystallinity of HA [38]. Importantly, these peaks are not clearly visible in the FTIR spectrum of EHA-1, EHA-2, EHA-3 and EHA-4 due to their relatively poor crystalline nature which agrees with XRD results. Broad absorption band centred at 3420 cm^{-1} and a small band in between 1600 and 1645 cm^{-1} are ascribed to the stretching and flexural modes of adsorbed H_2O molecules and they are observed for all samples. The band at 1420 cm^{-1} and a small peak at 879 cm^{-1} are assigned to carbonate (CO_3^{2-}) group, which is acquired from the atmosphere during sample preparation (alkaline condition). The observed positions of carbonate peaks indicate that it is substituted for phosphate group in HA and formed as B-type carbonated HA [39].

3.3. HRTEM

Fig. 3(a) and (b) shows the HRTEM images and selected area electron

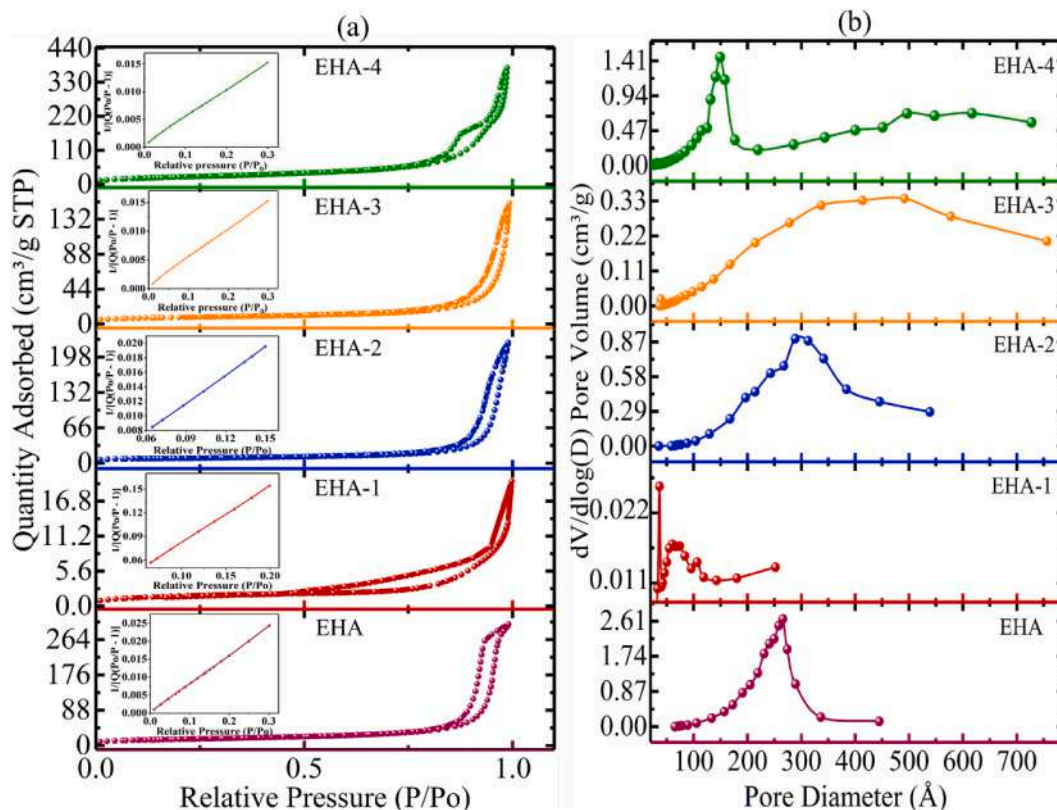

Fig. 7. (a) N_2 adsorption/desorption isotherm (inset BET surface area plot), (b) BJH pore size distribution of prepared samples

Fig. 8. Cell viability percentage of prepared samples with fibroblast NIH 3T3 cells

diffraction (SAED) pattern of EHA. HRTEM images of EHA clearly indicate that it consists of inhomogeneous rod like particles with clear boundaries. The average length and width of particles was calculated as 40 – 600 nm and 34 ± 10 nm respectively (Image J). SAED pattern of the EHA sample (Fig. 3(b)) reveals bright spots arranged in continuous ring which is owing to its polycrystalline nature and it is indexed with Miller's planes observed in XRD.

HRTEM, SEM images and SAED pattern of EHA-1 are shown in Fig. 3 (c) and (d). The SEM (inset in Fig. 3(c)) morphology of obtained EHA-1 sample shows the flower like structure with size of about 1.67 ± 0.12

μm . SEM observation of the sample synthesized using EDTA exhibited a flower like structure as reported in our previous work [34] which is shown in the inset of Fig. 3(c). A more close observation of an individual flake of the flower using HRTEM is shown in Fig. 3(c). Fig. 3(d) shows the SAED pattern of EHA-1 sample which is exhibiting continuous ring of diffused spots that represents the polycrystalline nature of EHA-1. Moreover it shows clear reflections from (402), (202), (102), (111), (002), (211), (310), (004), (321) and (222) Miller's planes of HA.

HRTEM pictures in Fig. 4(a) and (b) display the PEG assisted synthesized EHA sample (EHA-2). It exhibited rod shape with aggregates containing less number of nanoparticles of length and width 31 ± 8 nm and 8 ± 1 nm respectively. Remarkably, individual particles of EHA-2 sample contained pores of ~ 5 nm as can be seen from Fig. 4(b) (inset at top right corner). A magnified image of EHA-2 in Fig. 4(b) shows that the obtained nanoparticles are almost homogeneously sized. The SAED pattern of EHA-2 is made up of continuous rings with lucid spots revealing the formation of polycrystalline material.

From the HRTEM images of EHA-3 it is observed that the sample consists of highly agglomerated needle like nanoparticles having a length of about 32 ± 8 nm and width 3 ± 1 nm (Fig. 5(a)). EHA-3 exhibits polycrystalline nature which was confirmed from the lucid ring observed in the SAED pattern (Fig. 5(b)). HRTEM image (Fig. 5(c)) of EHA-4 exhibits highly aggregated nanorods of 68 ± 20 nm length and 10 ± 3 nm width. Fig. 5(d) shows the SAED pattern of EHA-4 containing bright spots arranged in ring pattern indicating the polycrystalline nature of the sample.

3.4. EDAX

The compositional analysis on the as synthesized powders was studied using EDAX. The prepared samples are composed of elements such as calcium (Ca), phosphorus (P), sodium (Na), magnesium (Mg), silicon (Si), carbon (C) and oxygen (O). The elemental composition of the synthesized samples examined by EDAX is given in Table 2. The Ca/

Fig. 9. FESEM micrographs of fibroblast NIH 3T3 cell adhered on the prepared samples disc surface.

P ratio obtained for the samples is 1.51, 1.42, 1.46, 1.49 and 1.37 respectively for EHA, EHA-1, EHA-2, EHA-3 and EHA-4. The obtained Ca/P ratio of the powder samples are less than 1.67 confirming that the synthesized samples are indeed non-stoichiometric HA.

Analysis of the elemental composition of chemically untreated eggshell was done by EDAX. The eggshell studied was found to be composed of elements such as calcium (13.8 at.%), phosphorus (0.3 at.%), sodium (0.9 at.%), magnesium (0.7 at.%), silicon (0.2 at.%), carbon (27.2 at.%), oxygen (55.9 at.%), fluorine (0.8 at.%) and iron (0.2 at.%). The eggshell was chemically processed to obtain HA, which contains trace elements such as magnesium, silicon and sodium. Trace elements in the prepared HA nanoparticles might be mostly contributed by the eggshell.

3.5. TG/DSC

TGA and DSC plots of the EHA, EHA-1, EHA-2, EHA-3 and EHA-4 samples are presented in Fig. 6. TGA plots of all the prepared samples revealed gradual weight loss due to the liberation of surface adsorbed water and carbonate molecules. All the samples showed three steps of weight loss, first exothermic weight loss observed in between ~ 34 and 180 °C for all samples is ascribed to the dehydration of the prepared samples and evaporation of physically/surface adsorbed water molecules. The second weight loss observed between ~ 180 and 900 °C is due

to the removal of chemisorbed water and gradual elimination of carbonate molecules. The final weight loss of all the samples observed in the temperature range of ~ 900 – 1200 °C corresponds to the decomposition of the HA phase into β – tricalcium phosphate (β -TCP) due to removal of the structural OH^- group. Table 3 shows the temperature and its corresponding weight loss percentage of the prepared samples. It is noted that EHA-1 showed high weight loss in first and second steps which clearly indicates it contains a large amount of water molecules and carbonate content.

3.6. BET

Fig. 7 shows the plots of N_2 adsorption-desorption isotherm, Brunauer–Emmett–Teller (BET) surface area (inset in Fig. 7(a)) and pore size distribution of the prepared samples. Herein, the BET surface area plot of all the samples showed a linear variation which pointed out the accuracy in the quantitative measurement of surface area. The BET surface area of the EHA, EHA-1, EHA-2, EHA-3 and EHA-4 samples was observed as 54.74, 5.97, 33.57, 87.96 and 30.38 m^2/g , respectively. In general, the surface area of a material mainly depends upon the particle shape and size [40]. The obtained results clearly state that HA prepared in the presence of organic modifiers can change the surface area by controlling the shape and size of HA nanoparticles. Herein, Fig. 7(a) shows adsorption isotherm of all the samples which revealed type IV

Fig. 10. Schematic representation of the formation of HA under microwave irradiation (2.2 kW) in the presence of different organic modifiers

physorption isotherm according to the IUPAC classification [41]. This result clearly represents that the prepared samples are mesoporous materials. Fig. 7(b) shows the pore volume and pore diameter of the prepared samples. The Barrett-Joyner-Halenda (BJH) method was used to calculate the pore volume of samples. The pore volume of EHA, EHA-1, EHA-2, EHA-3 and EHA-4 were found to be 0.47, 0.03, 0.35, 0.58 and 0.24 respectively. Average pore diameter was found to be 221.04, 079.87, 262.69, 279.83 and 181.36 Å for EHA, EHA-1, EHA-2, EHA-3 and EHA-4 samples, respectively. According to IUPAC classification, the observed hysteresis loop clearly shows that the EHA contains cylindrical pore channels whereas other samples have slit shaped pore channels [41,42].

3.7. Cytocompatibility

Fig. 8 displays the cell viability of fibroblast NIH 3T3 cells cultured with different dosages of prepared samples. It is obvious that the prepared samples exhibited good cell viability for the different dosages of the samples. All the examined samples exhibited cell viability of above 82%. Cell viability of the samples (EHA to EHA-3) decreased with increasing concentration of the samples but EHA-4 sample maintained cell viability above 98% for all concentrations. However, slight variation in the cell viability is observed between the samples which may be attributed to their internal characteristics.

3.8. Cell adhesion

Cell attachment on the disc surface of EHA is a vital prerequisite stage for the growth of cells, migration and other functions. Fig. 9 shows the FESEM micrographs of the cells cultured on prepared disc samples for 24 h. All the samples exhibit suitable cell attachment on the disc surface. However, the EHA-4 sample showed less cell attachment than the other four samples. The presence of trace ions (Mg, Si, Na and CO_3^{2-}) inherited from the eggshell is believed to significantly enhance the biomineralization, cell proliferation and osteogenic properties of HA [43,44].

In recent years, material scientists are interested in the microwave method of material synthesis since it is an efficient and quick way to synthesize inorganic nanoparticles. Recently, our research group has designed and fabricated a microwave reactor capable of operating at 2.2 kW. In the present study, we have conducted the synthesis of mesoporous HA nanoparticles with different sizes and shape using some organic modifiers (Fig. 10) employing the above mentioned custom built microwave reactor in 5 min.

During synthesis size and shape of the HA, particles can be controlled using organic modifiers. The organic modifiers such as EDTA, PEG and TSC interact with calcium ions to make complex forms. The polyamino carboxylic acid of EDTA (hexadentate unit) reacts with Ca^{2+} to form a Ca-EDTA complex [45], PEG is a weak chelating and non-ionic organic modifier and chelate the Ca^{2+} ions in the form of PEG-O- Ca^{2+} -O-PEG [46], while citrate ion reacts with Ca^{2+} ions to form calcium citrate complex [36]. These complexes reduce the availability of free Ca^{2+} ions

Fig. 11. Schematic diagram represents the different applications of various size and shape of HA nanoparticle

and inhibit the formation of HA at ambient temperature. The anionic organic modifier CTAB belongs to the soft template category; it, interacts with water to form positive charge micelles which react with the negatively charged PO_4^{3-} ions to form $\text{CTA}^+\text{-PO}_4^{3-}$ due to strong electrostatic interaction [14,47]. Under microwave irradiation or thermal impact, the reaction mixture containing calcium complex releases Ca^{2+} ions which immediately react with phosphate and phosphate complex releases PO_4^{3-} ions which abruptly react with calcium to form HA crystal with controlled size and shape. The mechanism of formation of flower like HA in presence of EDTA was previously reported by several researchers [45,48,49]. Jung Sang Cho et al., reported the spherical, rod and fibre like HA nanoparticles formed in presence of different concentration of PEG organic modifiers [50]. Xiaoying Jin et al., studied the formation of HA nanorods with various aspect ratio through the hydrothermal method in the presence of sodium citrate organic modifier [36]. YingJun Wang et al., explained the formation mechanism of HA nanorods in the presence of CTAB surfactant [51].

HA nanoparticles with different sizes and shapes find wide application in hard tissue replacement, drug/protein/DNA carrier, etc. Xin-Yu Zhao and co-workers reported that flower like nanostructured HA has high adsorption capacity of proteins like bovine serum albumin-165 mg/g, hemoglobin-164 mg/g and DNA (fish sperm DNA-112 mg/g) [52]. Further, it has exhibited pH dependent protein release behaviour, revealing that the flower like morphology is suitable for physio-pathological pH responsive drug carrier application. Rod like HA nanoparticles are reported to enhance the cell attachment and migration leading to osteogenic efficacy. For example, osteogenic bioactivity of the rod shaped HA nanoparticle studied by Yulin Li et al. showed that stem cells could efficiently adsorb on less crystalline nanorods that mimic the natural HA. Ca^{2+} and PO_4^{3-} ions released by the partial dissolution of the HA nanorods at an acidic lysosomal condition regulate the osteogenic activity of stem cells [53]. HA nanorods are reinforced as an

inorganic material in the composite scaffold to make bone substitutes for bone regeneration. In fact, HA nanorod addition in a polymeric material can increase mechanical properties and stimulate new bone formation [12]. Zandi et al. studied the biological and mechanical properties of HA nanorod reinforced gelatin composite scaffold fabricated using the freeze drying method. The obtained HA-gelatin composite scaffold increased the cell attachment and migration as compared to a pure gelatin scaffold [54].

Yubei Qiu et al. prepared bone morphogenetic protein-2 (BMP-2) loaded mesoporous HA nanorods mixed with silk fibroin/chitosan suspension and it was used to fabricate composite scaffold by freeze drying method. The presence of mesoporous HA nanorods induced *in vitro* osteogenic differentiation and promoted *in vivo* osteogenic efficacy. Furthermore, the mesoporous HA composite scaffold revealed the sustained release of BMP-2 and the concentration of BMP-2 release contributed to the desired bioactivity and improved osteogenic efficacy [55]. Li et al. reported the PEG surfactant assisted synthesis of HA nanorods where they introduced HA nanorods into polyurethane based injectable bone cement which showed enhanced bioactivity and mechanical properties towards osteoporosis management [56]. Also, Che et al. prepared composite bone cement using poly methyl methacrylate and rod like HA nanoparticles, which revealed an improved degree of bone mineralization and proliferation of bone progenitor cells [57].

On the other hand, nano HA is widely used in environmental applications because it reveals excellent adsorption, surface reactive and ionic exchange properties. For example, removal of Pb(II) ions from waste water by the sphere and rod shaped HA nanoparticles reported by Bharath et al. clearly indicated that HA nanoparticle of rod shape adsorbed more Pb(II) ions from waste water as compared to spherical one [58]. Varaprasad and co-workers studied the acidic blue 113 dye removal from waste water using rod like HA based hydrogel nanocomposite [59]. Inhibition ability of breast cancer cell growth by HA

nanoparticles of three different morphologies under *in vitro* conditions revealed that needle HA nanoparticles reduced the growth and proliferation of breast cancer cell lines by more than 73% [60]. Moreover, needle like HA nanoparticles has high surface charge, roughness and adhesion strength which significantly enable the growth of osteoblast (*in vitro*) and *in vivo* osteointegration efficacy of scaffold in rabbit model [61]. Thus, research community is showing more focus on obtaining HA nanoparticles with various size and shape to prepare bone substitutes with suitable properties for biomedical applications. The schematic shown in Fig. 11 clearly reveal the significant role of size and shape of HA nanoparticles for various applications.

The size and shape of HA particles synthesized in the presence of the organic modifiers employed in the present study by different methods reported in the literature is listed in Table 4. As observed from the table, the time consumed for the synthesis is from few hours to several hours when the method adopted was hydrothermal, reflux, precipitation, etc. The microwave reactor we utilized consumed just 5 min for the synthesis process. Therefore, eggshell derived HA nanoparticles with suitable characteristics for various biomedical applications can be rapidly synthesized by choosing appropriate organic modifier and our custom built microwave reactor.

4. Conclusion

In summary, we have synthesized mesoporous carbonated HA using eggshell biowaste as the calcium source via a custom built pilot scale microwave reactor in 5 min in the presence and absence of organic modifiers, employing the optimized parameters from our previous work. HA synthesized without organic modifier resulted in inhomogeneous sized rods of HA. While the presence of organic modifier controlled the physicochemical properties like particle size, surface area, morphology, mesoporous nature, etc. Micron sized flower like HA formed with EDTA as the modifier. However, the other organic modifiers produced rods or needles of typical size less than 100 nm. The *in vitro* cytotoxicity experiments of the prepared HA samples on fibroblast NIH 3T3 cell line clearly evidenced their excellent biocompatibility and revealed good cell attachment. Thus the custom built pilot scale microwave reactor is capable of producing eggshell derived HA rapidly with favourable characteristics in the presence of a suitable organic modifier for developing bone fillers, drug/protein delivery carriers, and tissue engineering scaffolds.

ABSTRACT:

The use of thermoplastic resins for the denture base began around 1950s. Flexible removable denture prosthesis are also known as non-clasp, metal-free, or clasp free dentures. Flexible denture base material is a viable option to treat various partial and completely edentulous conditions. The current article describes the use of thermoplastic resin material as a treatment option for different clinical situations.

Keywords: - flexible dentures, Valplast, thermoplastic resin

Received: 10 April, 2021

Accepted: 15 May, 2021

INTRODUCTION

Dentures are a mode of treatment for replacing missing teeth since 700 BC. Improvement in the quality of materials used for fabricating dentures was a continuous process to meet the patient's demands and apply them for different clinical situations. Implants and fixed partial dentures are

more preferred and advantages over removable partial dentures but, in some clinical conditions, removable partial dentures may be the only treatment option. Other than a conventional removable dental prosthesis, flexible partial dentures are superior in terms of esthetics and comfort.

COMPOSITION

It was first introduced as Valplast and Flexiplast to dentistry in 1956 ^(1, 2)

Component	Role
Polyamide nylon thermoplastic material	Resin derived from dicarboxylic acid, diamine, amino acid and lactams transparency, high impact resistance,
Elastomeric resins	Flexibility
Glass fibers	Strength

ADVANTAGES

1. Soft and inherent flexibility.
2. Clinically unbreakable.
3. The translucency of the material picks up the tissue tone, making it almost impossible to detect in the mouth
4. Good biocompatibility: Because it is, free of monomer and metal.
5. Absorb small amounts of water to make the denture more soft and tissue compatible.
6. High impact resistance
7. Color stability
8. High creep resistance

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

9. High fatigue endurance
10. Excellent wear characteristics
11. Good solvent resistance
12. No porosity, so bacteria cannot build up within it.
13. No biological material build up or odors.
14. Low water sorption & good dimensional stability
15. The microcrystalline structure is easy to finish and polish.
16. Will not cause any sore spots as seen with rigid acrylic dentures.
17. Flexible dentures may be used as an alternative treatment plan in rehabilitating the anomalies such as Ectodermal dysplasia.
18. Free movement is allowed by the overall flexibility and can, therefore, be referred to as “a built in stress breaker”.

DISADVANTAGES

1. Flexible prosthesis is difficult to relin and rebase
2. Prone to staining by various ingredients of food, tea and coffee if it is not appropriately polished or cleaned by the patient regularly.
3. Acrylic teeth do not bond chemically with flexible denture base material. They are mechanically retained by making T shape holes- diatorics into

which denture base resin flows to retain teeth mechanically. This is known as Retento-Grip tissue bearing technique. ⁽³⁾

COMMERCIALY AVAILABLE PRODUCTS: - Valplast, Duraflex, Flexite, Proflex, Lucitone, Impak.

INDICATIONS: ⁽⁴⁾

1. Complete dentures, partial dentures, and in cases with bilateral in-operable undercuts when pre-prosthetic surgery is contraindicated.
2. Patients allergic to acrylic monomers
3. Used as an alternative treatment plan in rehabilitating the anomalies like Ectodermal dysplasia.
- a. Special applications-
4. TMJ splints
5. As cosmetic veneers/gum, veneers to mask gingival recession in periodontally involved teeth,
6. Mouth guards in sports,
7. Bruxism splints/ Night guards
8. Obturators
9. Orthodontic retainers.

COMPARISON WITH CONVENTIONAL ACRYLIC

Rigid denture base	Flexible denture base
Brittleness of PMMA- so frequent fracture occurs	Not brittle- Clinically unbreakable
Monomer allergy	Good biocompatibility: because it is free of monomer and metal
Irritation to mucosa	More comfortable, not irritant to mucosa
Rigid Difficult to insert in undercut areas	Soft and inherent flexibility therefore engages undercuts for retention
Less aesthetics, metal clasp	Better aesthetics, aesthetic clasps
Longer fabrication time	Shorter fabrication time
Chemical bond between acrylic teeth and acrylic denture	Mechanical retention between acrylic teeth and denture. De-bonding is a major disadvantage
Can be relined and repaired	Usually cannot be relined and repaired

CASE REPORT 1

A 58 years old male patient reported to the Department of Prosthodontics with a chief complaint of multiple missing teeth in the upper and lower arches. Intraoral examination revealed missing 17, 16, 26 in maxilla and missing 37,34,35,43,44,45,46 in the mandible (fig 1a, 1b, 1c). The denture bearing area was irregular in the mandible with bony undercuts hence, a flexible removable partial denture was advised and cast partial denture was advised for maxilla (fig 2a 2b). The dentures were fabricated and the patient was satisfied with the aesthetics and comfort of the dentures (fig 3, 4).

1. a) intra oral frontal view b) intra oral right lateral view c) intra oral left lateral view

2.a) cast partial denture -maxilla b) flexible removable partial denture -mandible

3.a, b) intra oral views after insertion of prosthesis

4. a, b) intra oral lateral views after insertion of prosthesis

CASE REPORT -2

A 16-year-old female patient reported to the Department of Prosthodontics with a chief complaint of multiple missing teeth. On intra oral examination 17,14,13,12,22,23,24,25,27,37,31,41,47 were missing (fig 5a,5b,5c). Radiographic examination revealed the absence of teeth buds of missing teeth and the patient was susceptible of Ectodermal dysplasia. To enhance comfort to the patient, as it can be built quite thin, a flexible removable partial denture (fig 6a, 6b, 6c) was suggested for maxilla until the patient achieved skeletal maturity after which the patient is suggested for implant therapy for missing teeth.

5a) intra oral frontal view b) intra oral right lateral view c) intra oral left lateral view

6 a, b) flexible denture c) intra oral view of denture

CONCLUSION

Selection of an optimum prosthesis suitable for a clinical situation depends on the skill of the clinician. Partially edentulous condition can be rehabilitated using many advanced treatment options including implants. In challenging situations where there are tilted teeth and deranged occlusion, bony undercuts may complicate the treatment plan. Flexible dentures will fulfil the clinical demand of rehabilitation in such conditions. Flexible dentures were rarely opted by few patients and the clinician but nowadays it has become an elective treatment option.

Customized Lubricating Eye Prosthesis - A Case Report

Mesari Koteswara Rao, K. Krishna Kishore, M. Suresh Babu, J. Ravi Rakesh Dev, H. Koteswara Rao

Department of Prosthodontics, Sibar Institute of Dental Sciences, Takkellapadu, Guntur, Andhra Pradesh, India

ABSTRACT:

Loss of an eye is an emotional and psychological problem to the human being. An ocular prosthesis was fabricated to restore the lost anatomical structure and to correct the defect of the anophthalmic sockets. The tear reflexes do not function at optimal levels in anophthalmic sockets which make prosthesis wear uncomfortable. In this case report presents an innovative hollow ocular prosthesis with functional lubricant reservoir which upon normal blinking would draw the lubricant from the reservoir through an exit hole by the blinking action creates capillary pressure which spreads over the prosthesis allowing a comfortable and long duration of prosthesis wear.

Keywords: Anophthalmic sockets, lubrication, capillary pressure, ocular prosthesis

INTRODUCTION:

Physical defects that compromise appearance or function which prevents an individual from leading a normal life usually prompt the individual to seek treatment that will reinstate acceptable normally.

The loss of an eye impairs the patient's visual function, yet also results in noticeable deformity. A prosthesis should be provided as soon as possible to raise the spirit and ease the mind of the afflicted.

The fundamental objective in restoring the eye with a cosmetically acceptable prosthesis enables to cope better to face the outside world.

In addition to appearance, comfort is also a prime consideration to most wearers. Due to lack of lubrication in patients with anophthalmic sockets¹ blinking and tear reflexes are at optimal levels which lead to dryness, discomfort, irritation, bacterial infections².

Design of hollow ocular prosthesis with functional lubricant reservoir

CASE REPORT

A 28-year-old male patient reported to the Department of Prosthodontics for prosthetic rehabilitation of his lost right eye. On eliciting history, it was found that the patient had accident to his right eye, which necessitated a surgical evisceration of the eye. Clinical examination revealed a completely healed right eye socket. His left eye had normal vision. The patient had no other relevant medical history.

Procedure

The impression was made by injecting alginate impression material into the defected eye by using 5ml syringe. The patient was asked to move his eyes in all directions to facilitate flow of impression material into all aspects of the socket. Then, the patient was asked to look directly at a fixed point six feet away at the level of eye allowing impression of the site with the muscles in neutral gaze position.

- Impression is enclosed with light body, putty then it was indexed for exact location of borders and easy removal of wax pattern.

Wax try in

Flasking procedure

Hollowing of prosthesis by removing salt and placing rubber cup in postero superior aspect of prosthesis.

Placing artificial lubricant and capping the prosthesis was done

Preoperative and postoperative pictures of the patient

DISCUSSION:

Anophthalmic sockets does not had blinking and tearing mechanisms of eye socket because they do not operate at all or are insufficient to allow the patient comfortable prosthesis use. In addition to the problem of dryness, continuing problems of bacterial infections are suffered by many prosthesis users.

This article is mainly to fabricate hollow ocular prosthesis with functional lubricant reservoir in an attempt to solve problems of inadequate lubrication such as dryness, discomfort, irritation, bacterial infections, and mucus deposition over prosthesis

thereby allowing long duration of the use of the prosthesis. The patient is instructed to load the lubricant into the reservoir via the removable cap. During the normal blinking action, the upper eyelid creates a negative pressure which draws the lubricating fluid from the reservoir to the anterior surface of the prosthesis through the exit hole which spreads over the prosthesis by blinking action. The hollow ocular prosthesis also improves comfort by reducing the weight of the prosthesis. The lubrication also gives a wet looking anterior surface which gives a life-like appearance. In cases of bacterial infections

instead of lubricant, antibacterial eye drops can be loaded in the reservoir.

Lost wax technique is used in fabrication of hollow ocular prosthesis to reduce the weight of the prosthesis. In this case report, the technique presented to fabricate the lubricant reservoir by lost salt technique is simple, easy to construct, affordable, uses readily available materials, is functional, and cleansable. However, it has certain drawbacks such as the design might not be feasible in patients with shallow sockets, difficulty in gauging resin thickness, and it depends on patient compliance for loading of lubricant reservoir.

This case report presents a simple technique to place and to match the exact position of the iris by using the life size photograph of the patients left eye to ensure that the same position of iris is achieved in the final prosthesis as it was during try-in thus avoiding squinted eye appearance. It can also be used to assess the orientation of visual axis during try-in.

A modified curing cycle called as reverse curing cycle was followed ensuring elimination of residual monomer by curing at an increased temperature. Veined acrylic is used for characterization and to match the natural eye color. Hollowing of prosthesis by removing salt and placing rubber cup in posterior superior aspect of prosthesis. Placing artificial lubricant⁴ and capping the prosthesis was done. Then exit hole was created on the anterior superior aspect of the prosthesis. During the normal blinking action, the upper eyelid creates a negative pressure which draws the lubricating fluid from the reservoir to the anterior surface of the prosthesis through the exit hole which

spreads over the prosthesis by blinking action. The patient is instructed to load the lubricant into the reservoir via the removable cap.

CONCLUSION:

Success of the ocular prosthesis largely depends on the artistic skills of the operator and maintenance and wearing of the ocular prosthesis by the patient. Through this technique, hollow ocular prosthesis with functional lubricant reservoir presented in this case report can help solve the multiple problems associated with dry eye socket, as a result provide, comfort for the longer duration of wear of the ocular prosthesis.

ABSTRACT:

Introduction: Several studies have shown that chronic treatment with salbutamol sulfate and inhaled corticosteroids in asthma patients has increased the risk of dental caries and bacterial plaque accumulation, which calls for these patients' special attention by medical and dental health professionals^{1,2,3,4}. **Materials and methods:** In this prospective, an invitro study was done to evaluate the surface roughness changes and color stability of three different dental resins i.e., heat cure acrylic resin I (**ACRYLYN – H, PINK**), cross linked tooth colored acrylic resin (**BRULON INTERNATIONAL, shade A1**) and bis acrylic temporary resin (**PROTEMP 4, shade A1**). up on exposure to salbutamol-based nebulizer. The outcome parameters assessed at the end of 30days, 60days, 90days. Statistical analysis was performed using SPSS version 20 software. **Results & Conclusion:** The study revealed that the inhalation of salbutamol sulfate significantly ($p < 0.01$) affected the surface roughness and color stability of all three resins.

INTRODUCTION

Salbutamol sulfate is a selective β_2 agonist which is administered in inhaler form, that elicit fast onset bronchodilation in reversible airway obstruction¹. Polymethyl methacrylate (PMMA) is most commonly used denture base resin as well as denture teeth because they are economical, easy to manipulate, fabricate, and repair compared to other materials available for fabrication of denture². Studies by Quirynen et al. showed that an increase in the surface roughness of resin strips above the roughness average (R_a) value of $2\mu\text{m}$ resulted in the bacterial colonization³. The discoloration of treatment restorations when used for longer duration can result in an esthetic problem. Minimizing change of color is a factor that should be used in the selection of materials and techniques⁴. Studies revealed that the antiasthmatic medication exerts effects on dental caries and periodontal disease⁵. However, there were no such studies which evaluated the effect of antiasthmatic drugs on different resin materials. This study aimed to investigate the effect of salbutamol sulfate inhalation in a mist form on surface roughness and color stability of dental resins.

The null hypothesis was that no significant changes in the surface roughness and color of resin materials would occur after salbutamol sulfate exposure.

MATERIALS AND METHODS

Round metal molds of dimensions 10×2 mm were taken to fabricate specimens. Sixty wax patterns for groups I and II were fabricated by pouring molten modeling wax into the customized mold space of dimensions 10×2 mm and was allowed to solidify, then retrieved from the mold for investment. Dental stone was mixed according to the manufacturer's instructions and poured into the dental flasks' base. The wax patterns were invested into the dental stone to half of their height. After the dental stone is set, cold mold seal was applied and is allowed to dry. Dental stone is then mixed and poured into the flask until it is completely filled to form the second pour. After the complete set of the stone, dewaxing was done by immersing the flasks in the dewaxing unit at 100°C for 4 minutes. The flasks were then removed from the dewaxing unit, and residual wax was flushed out. After the mold is dried, cold mold seal was applied, and the heat polymerized resin (group I) and cross-linked acrylic resin (group II) materials were mixed in a porcelain jar separately according to the manufacturer's instructions (21 g of polymer to 8 ml monomer). The heat-cured acrylic resin and cross-linked acrylic resin were packed into the stone mold in the dough stage in both the compartments, and the flasks were placed under hydraulic pressure upto 1000 psi. The resin was allowed to bench cure for 30 minutes. The flasks were removed from the hydraulic press and were attached to the clamps and allowed to undergo short- time polymerization in a water bath

at 72°C for 1.5 h, followed by 30 min boiling in 100°C water in a dental acrylizer. Flasks were allowed to cool down to room temperature and then removed from the water bath and deflasked. The samples were then retrieved carefully, trimmed by using the acrylic trimmer, and all samples (group I and II) were finished with no. 220, 600, 800 silicone carbide grinding papers and polished with 1000 grade abrasive waterproof paper with intermittent movements lasting 10 s each, rinsed with tap water, and air dried. Specimens were polished using a slurry of water and pumice with a brush wheel.

Group III (Protemp 4) Sample fabrication:

The Protemp 4 (3M Deutschland GmbH, Germany. Lot NO: 3384978) provisional material, which is supplied in cartridge form as base and catalyst pastes were dispensed into the metal mold space. A glass coverslip was placed immediately above the template in order to achieve a uniform thickness (2mm) of the sample. After the final set (5 minutes), the glass coverslip and mold were separated, and the samples were retrieved. Later the samples were polished and finished with pumice.

A total of 30 samples were prepared in the same method and were stored in artificial saliva, same as the above two groups.

The specimens of all (group I, II, III) were then randomly divided into two groups ($n = 15$), i.e., the control group and the test group, and were named as group IA, IB, IIA, IIB, IIIA, IIIB. All the samples were stored in containers with a lid filled with artificial saliva (**Fig no:1**). The test specimens were stored using a supporting device.

Fig no :1 control group samples in artificial saliva

Salbutamol sulfate application in a mist form

During the salbutamol sulfate application, the test specimens were placed into a chamber using a supporting device that would allow the samples to remain in a vertical position so that the greater part of their surface would be exposed (**fig no:2**). After exposure to each respule, the test specimens were immersed in artificial saliva, brushed with toothpaste (Colgate Total) and washed under running water to simulate clinical conditions; they were then exposed to the next respule. Each sample was treated with 20 mg respule each day as it is the average daily dose for asthma patients. Readings were noted at the end of 30,

60, 90 days' time intervals.

Fig no 2 Exposure to salbutamol sulfate

Method of evaluating surface roughness:fig no 3

Before each reading, the samples were rinsed under running water for 1 minute and dried with a blotting paper. The surface roughness values (Ra) of the specimens were measured with Talysurf SurfTester (SJ-210P, Mitutoyo Corp, ISO 1997,0.02 inches/sec, Kawasaki, Japan). Three readings were taken from each sample at the center of the specimen, 1mm to the right and 1mm to the left, and the mean Ra value was calculated for each sample. Readings were noted on the control and test group specimens of all groups I, II, III at the end of the 30th day, 60th day, 90th day

Fig no 3 Measuring surface roughness with surface roughness tester (Mitutoyo)

Method of evaluating color stability: (fig no:4)

Color data was recorded using a spectrophotometer (Datacolor spectrum 600TM) by calibrating with a standard calibrator before recording the color measurements. The diameter of the measurement aperture was 6.6mm; the illumination and light beam angle was 90⁰. Color changes were examined for each specimen based on color specifications using the CIE L*a*b* color space system. The CIE L*a*b* system represents a three-dimensional color space with components of lightness (L), red-green (a), and yellow- blue (b). In terms of ΔE values, color data measurements were noted at the end of 30, 60, 90-day time intervals. All color measurements were observed from the central part of each specimen. Values of ΔE ≥3.3 were considered to be clinically unacceptable. To relate the color differences (ΔE) to the clinical

environment, the color data was quantified by the National Bureau of Standards (NBS), United States units, with the following formula: NBS units = ΔE ×0.92. Critical marks of color differences according to the NBS are classified as trace (T): 0.0–0.5; slight (S): 0.5–1.5; noticeable (N): 1.5–3.0; appreciable (A): 3.0– 6.0; much (M): 6.0–12.0 and very much (V): >12.0.

STATISTICAL ANALYSIS

The statistical analysis was performed using software SPSS version 20.0 (I.B.M., NY, U.S.A.). Paired t-test was carried to know the mean comparisons of surface roughness between the test and the control groups of three materials at three different time intervals. One way ANOVA was performed to know the between group comparisons of surface roughness, which was followed by post hoc tests for multi pair wise comparisons with the statistical significance value set as p <0.05. One way ANOVA was done to compare the means of color stability between the three groups at three different intervals followed by Tukey post hoc test with the statistical significance level set as p<0.05.

RESULTS

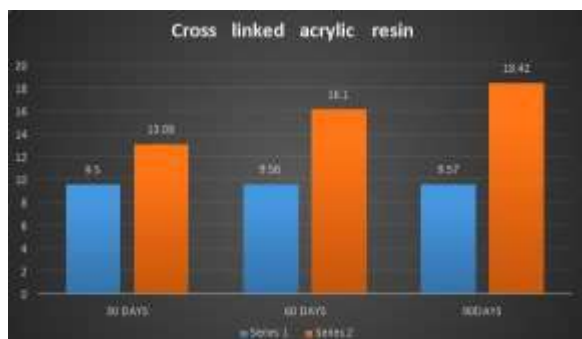

GRAPH 1: Ra Mean values comparison of Group 1 test and control samples (HEAT CURE ACRYLIC RESIN) during different time intervals.

Graph 1 represents the comparison of mean values of Group 1(heat cure acrylic resin) control and test samples, which were obtained during different time intervals. The bar graph represents that there were significant differences observed in test group samples from 30 to 90 days. The lowest mean value was obtained in the control group samples at all time intervals, and the highest mean

value was obtained in the test group samples.

GRAPH 2: R_a Mean values comparison of Group 2 test and control samples (CROSS LINKED ACRYLIC RESIN) during different time intervals.

Graph 2 represents the comparison of mean values of Group 2 (cross linked acrylic resin) control and test samples, which were obtained during different time intervals. The bar graph represents that there were significant differences observed in test group samples from 30 to 90 days. The lowest mean value was obtained in the control group samples at all time intervals, and the highest mean value was obtained in the test group samples.

GRAPH 3: R_a Mean values comparison of Group 3 test and control samples (BIS -ACRYLIC RESIN) during different time intervals.

Graph 3 represents the comparison of mean values of Group 3 (Bis- acrylic resin) control and test samples, which were obtained during different time intervals. The bar graph represents that there were significant differences observed in test group samples from 30 to 90 days. The lowest mean value was obtained in the control group samples at all time intervals, and the highest mean value was obtained in the test group samples.

GRAPH 4: ΔE Mean values comparison of Group 1,2,3 during different time intervals.

Graph 4 represents the comparison of ΔE mean values of groups 1,2,3 at three different time intervals. The bar graph represents that there were significant differences

observed in group 3 samples from 30 to 90 days. The lowest mean value was obtained in the group 1 samples at all time intervals, and the highest mean value was obtained in the group 3 samples

DISCUSSION

Bronchial asthma is a globally significant disease. This chronic lung disease has a detrimental effect on the oral cavity, like the reduction of salivary secretion, change in salivary composition and pH. Inhaled β_2 agonists provide a favorable environment for the growth and multiplication of microorganisms causing dental caries (Streptococcus mutans and Lactobacilli) by decreasing salivary secretion^{6,7}. However, the effect of these antiasthmatic drugs on different dental resins has not been studied.

This study aimed at evaluating the effect of antiasthmatic medication in a mist form on change in surface roughness and color stability of heat cure acrylic resin, cross-linked acrylic resin, and bis acrylic resin materials. In this study, both the test and control group samples of all three materials were stored in artificial saliva and were brushed in order to equalize the effect of absorption as well as roughness. This study evaluated the effect on three resins by antiasthmatic medication through a nebulizer for a period of 90 days, and tests were performed at the end of 30, 60, 90 days intervals.

At the end of 30 days of exposure to the mist form of antiasthmatic medication, it was observed that the roughness has significantly increased for heat cure acrylic resin followed by cross-linked acrylic resin and least for bis acrylic resin.

At the end of 60 days, by observing the trend of R_a values it was noted that the change of roughness is more for heat cure acrylic resin when compared to the other two groups of resins.

At the end of 90 days, the R_a values of test group samples have increased. The roughness difference from initial period to final period is comparatively more for heat cure acrylic resin and cross-linked acrylic resin than bis acrylic temporization resin. Results of the present study showed that the inhalation of salbutamol sulfate significantly ($p < 0.05$) affected the surface roughness of all three resins.

Hence the structural properties and finishing procedures of restorative materials affected the surface roughness characteristic⁸. The difference could be the chemical characteristics of the material itself.

This less roughness change of bis acrylic resins can be credited to the fact stated by Balkenhol et al. that bis-acryl composites contain multifunctional monomers, which increase strength due to cross linking. According to Rawls HR, the 3-D network of cross-linked polymer chains forms a rigid structure for the composite resins as the entire network acts as one unit. This phenomenon enhances the surface characteristics of bis-acryl composite resins. Surface hardness is one of the good indicators of resistance to wear and surface deterioration⁹. Diaz-Arnold found that all bis-acrylic resin composite materials exhibit superior microhardness over the traditional methyl methacrylate resins throughout a 14-day interval of investigation¹⁰. It should also be pointed out that in addition to monomers such as bisphenol-A-diglycidyl dimethacrylate (Bis-GMA) and triethylene glycol dimethacrylate (TEGDMA), the bis-acrylic resins have an organic matrix and inorganic filler particles. Monomers and their derivatives are tend to provide better mechanical properties, reduction in polymerization shrinkage, and excellent polishing properties^{11,12}.

Antiasthmatic inhalers may produce some side effects. The manufacturers report that mouth or throat irritation is a common oral side effect of the drug¹³. Surface roughness is an important clinical criterion of restorative materials. Increased roughness may lead to more plaque retention, bacterial adherence, and gingival irritation¹⁴. The results of the present study may indicate the higher caries susceptibility of asthma patients undergoing treatment with inhalers and nebulizers. During the use of this medication, the drug is applied as a pressurized metered-dose aerosol unit for oral inhalation, which contains a microcrystalline suspension of albuterol sulfate ethanol and oleic acid. These substances cover the teeth and periodontal tissues during inhalation and may remain as a residue after inhalation. Thus, patients using inhalers and nebulizers should be advised to implement more precautionary oral hygiene measures and have their caries activity and periodontal health status regularly examined. Generally, it is advised to rinse the mouth immediately after using the inhaler¹⁵. Temporary restorations are intended for the period between tooth preparation until insertion of the final prosthesis. Even during the time when interim restorations are being present in the mouth, esthetics are important¹⁶. Color stability is important for the esthetics of long-term provisional restorations and has been previously studied in vitro for a variety of interim materials. Proprietary variations in the chemistry, such as size distribution of the PMMA particles, the polarity of

the monomers, color stability, and efficiency of the initiator system for provisional resins, may lead to different degrees of polymerization, water sorption, and consequently, color stability¹⁷ as highlighted by Mazaro et al., the mixture of monomers may affect color stability, considering that most of the bis-acrylic resin polymers are more polar than acrylic resin (PMMA) polymers. These chemical characteristics increase the affinity of bis-acrylic resins for polar liquid molecules, and consequently, facilitates greater sorption of substances that interfere in the color stability of the materials¹¹.

In the current study, inhalation influenced the color of all three resins. This discoloration may possibly be due to the active ingredient of the inhaler nebulizer, which contains a $(C_{13}H_{21}NO_3)_2H_2SO_4$ sulfate group. The ingredients of this drug may affect the sulfate group. The ingredients of this drug may affect the surfaces of the dental materials by forming a pellicle matrix that provides an acidic environment, thus promoting demineralization and increasing surface roughness and discoloration¹⁸.

To relate the color differences (ΔE) to the clinical environment, the color data were quantified by the National Bureau of Standards (NBS)⁴¹, United States units, with the following formula: NBS units = $\Delta E \times 0.92$. Critical marks of color differences according to the NBS are classified as trace (T): 0.0–0.5; slight (S): 0.5–1.5; noticeable (N): 1.5–3.0; appreciable (A): 3.0–6.0; much (M): 6.0–12.0 and very much (V): >12.0. When the mean ΔE values of the specimens were converted to NBS units, in the present study tooth colored cross-linked acrylic resins and bis acrylic resins exhibited a noticeable (N) difference after inhalation, while heat cure acrylic resins were classified as trace (T) to slight (S) at the end of 90 days. Moreover, studies conducted by Gujjari et al., and Mazaro et al.,¹² found that PMMA is more color stable than bis-acryl composite resin, as PMMA showed lower color change values as compared to bis-acrylic resin for cola and coffee solutions. This happens because the PMMA-based materials have a more homogeneous composition, and consequently, the capacity to absorb and adsorb solutions, which may have a direct influence on color stability. Because of the heterogeneity of bis-acrylic resins, the pigmented solution is capable of infiltrating into the midst of small particles of material, thus causing a greater level of pigmentation^{20,12,21}.

Thus, the results of this study indicate that the color stability and surface roughness of all the three types of resins were influenced by asthmatic medication in a mist form and also the exposure interval.

However, the present study has certain limitations as it could not completely simulate the oral environment since the results may vary due to the neutralizing effect of saliva, thermal changes of oral cavity and food, food colorants, microbes present in the oral cavity, etc.,

Furthermore, the dentures have biplanar surfaces which attract more stains rather than flat surface specimens altering the observed results.

To overcome the limitations of this study, dentures of asthmatic patients should be evaluated.

CONCLUSION

The study revealed that the inhalation of salbutamol sulfate significantly ($p < 0.01$) affected the surface roughness and color stability of all three resins.

ABSTRACT:

Introduction: The optimal achievement of osseointegration is multi-factorial which depends on the density and quality of bone, surgical techniques employed, and the design of the implants. Primary stability is one of the fundamental parameters that determine the success of osseointegration. A multitude of new macro and micro-designs have evolved over the years. However, the true influence of shape on primary stability is still surrounded by controversies. **Materials and methods:** This prospective, double-blind, randomized clinical trial was done among 20 subjects, aged between 25 and 60 years, demonstrating a motivation to receive an implant for replacement of the missing teeth. Systemically healthy subjects demonstrating adequate height and width of D2 type of bone were included in the study. The study subjects were then randomly allocated to tapered and cylindrical implant groups. Primary stability, crestal bone loss, bleeding on probing, and mucosal thickness were the outcome parameters assessed at baseline, 3 months, and 6 months. Statistical analysis was performed using SPSS version 20 software. **Results:** There was a statistically significant difference in the primary stability between the study groups with higher mean values observed in the tapered implants group (76.2 ± 1.39 vs 61 ± 3.12 ; $p=0.001$). While differences in crestal bone loss were observed between the groups at 3 months and 6 months follow-up visits, no differences were noted in the mucosal thickness and bleeding on probing. **Conclusion:** The study results demonstrate that tapered implants exhibit higher primary stability and lesser crestal bone loss compared to cylindrical implants.

Keywords: Cylindrical implants, osseointegration

INTRODUCTION:

Oral rehabilitation with dental implants has gained prominence over the years for both partially and completely edentulous in light of the improved success rates with these treatment options. The optimal achievement of osseointegration is multi-factorial which depends on the density and quality of bone, surgical techniques employed, and the design of the implants.¹ It is the combination of these factors which influences the primary stability of an implant after implant placement.² It has been well established in the

literature that primary stability is one of the fundamental parameters that determine the success of osseointegration.³ Attempts have been made to modify the implant designs in such a manner that contributes towards an improvement in the primary stability by maximizing the contact area of the implant with the bone.⁴ The frequently used designs are the cylindrical and tapered implants. Unlike cylindrical implants, the tapered implants demonstrate a consistent reduction in diameter as we proceed towards the apex. When this narrowing starts from the shoulder of the implant and

GUNTUR-522509, A.P., India.

53

continues till the apex, the implants are categorized as fully-tapered differentiating them from those implants where the taper is restricted to cervical, middle, or apical parts.⁵

Primary stability, length of the implant, diameter, shape, thread design, etc all these factors contribute to osseointegration which promotes implant success.⁶ However, the true influence of shape on primary stability is still surrounded by controversies. With this background, the aim of this study was to evaluate the influence of implant design on primary stability and hard, soft tissue changes following implant placement between tapered and cylindrical implants.

MATERIALS AND METHODS:

This prospective, double-blind, randomized clinical trial was done among 20 subjects, aged between 25 and 60 years, demonstrating a motivation to receive an implant for replacement of the missing teeth. The sample size was calculated using G*power 3.1.9.4 software to detect an effect size of 1.4 using the Mann-Whitney U test at 80% power and an alpha error of 5%. The ethical approval for this study was obtained from the institutional ethical committee (Pr.134/IEC/SIBAR/2018). The study was conducted between May 2019 and July 2020. Informed consent was obtained from those participants before conducting the study. Systemically healthy subjects demonstrating adequate height and width of D2 type of bone were included in the study. Pregnant women, lactating mothers, smokers, subjects with uncontrolled diabetes or bleeding disorders, and severe bruxism were excluded. Oral prophylaxis was done for all the study subjects. Clinical evaluation of edentulous sites receiving implants was followed by a radiographic examination by using intraoral periapical radiographs, cone-beam computed tomography (CBCT). Diagnostic casts were made to evaluate the intra-arch space. In order to obtain an ideal position for implant placement, surgical guides were fabricated using acrylic resin. Bleeding on probing was assessed using a pressure-sensitive probe (0.5, 5.5, 8.5, 10.5mm) at baseline, 3rd, and 6th month postoperatively. The probe is passed along the gingival sulcus with the force of 0.25N/cm wait for 30 seconds to score the bleeding index. Mucosal thickness was assessed by using endodontic file no 20 with a rubber stopper. The file is inserted at the midpoint of the attached gingiva between the mucogingival junction and an imaginary line from adjacent tooth CEJ.

Prior to implant placement, subjects were advised to perform mouth rinsing with 0.12% chlorhexidine. After administration of 2% lignocaine with 1:80,000 adrenaline, mid crestal and reliving incisions were given and a full-thickness mucoperiosteal flap was

reflected and Point of entry was gained through a guiding hole made in the surgical guide using a precision drill. The preparation was done with the conventional drilling method in a sequential manner as instructed by the manufacturer (2.0, 2.4/2.8, 3.2/3.65) with the help of a physio dispenser at a speed of 800-2000 rpm. Preselected implants of 10mm length and 3.75 mm width were threaded into the prepared site at a low speed of 25 rpm at the crestal bone level using a handpiece/ratchet with an insertion tool. After placement, the primary stability of the implant was assessed with an osstell peg using a resonance frequency analyzer (Osstell) by attaching a transducer probe to the implant. In both the buccolingual and mesiodistal directions, ISQ measurements were obtained. The mean of the highest measurements in each of the two directions was considered as the ISQ measure for the implant. Soft tissue flaps were approximated using 3-0 silk. The marginal bone level was radiographically assessed at this time. The antibiotic and anti-inflammatory medication was advised for all the study participants along with chlorhexidine mouth rinse for one month. Sutures were removed after 7 days and all the subjects were recalled after 3 months for the prosthesis. During the three-month follow-up visit for prosthesis placement, radiographic assessment of marginal bone loss, evaluation of the mucosal thickness, and bleeding on probing were done. Patients were again recalled three months after the placement of the prosthesis, and crestal bone loss, mucosal thickness, bleeding on probing were assessed. Figure 1 shows the study flow chart.

Statistical analysis was done using IBM SPSS version 20 software (IBM SPSS, IBM, Armonk, NY, USA). The normality of the data was assessed using Kolmogorov Smirnov test and the choice of statistical tests to analyze the study data was made accordingly. Mann-Whitney U tests were used to check the differences in the study parameters between the tapered and cylindrical implant groups at various time points. Repeated Measures Analysis of Variance (ANOVA) tests were used to check the changes in crestal bone loss, bleeding on probing, and mucosal thickness scores within each of the study groups with a change in time.

Figure 7: Evaluation of crestal bone loss at 3 months for cylindrical implant

Figure 8: Evaluation of crestal bone loss at 6 months for tapered implant

Figure 7: Evaluation of crestal bone loss at 6 months for cylindrical implant

RESULTS:

The mean age of the study participants was 48.34±9.41 years. There was a statistically significant difference in the primary stability between the study groups with higher mean values observed in the tapered implants group (Table 1). At baseline, there was no crestal bone loss and bleeding on probing in both the study groups. The mean mucosal thickness at baseline in the tapered implants group was 0.92±0.13 mm, while it was 1.03±0.16 mm in the cylindrical implants group (Table 1).

Table 2 gives a comparative account of the crestal bone loss, mucosal thickness, and bleeding on probing at 3 months follow-up between tapered and cylindrical implants groups. Crestal bone loss on the mesial side, distal side, and the overall scores were compared separately between the study groups. None of the study parameters demonstrated significant differences between the study groups at 3 months follow-up. The magnitude of crestal bone loss on the mesial, distal sides and the overall bone loss values were significantly higher in the cylindrical implants group at the 6 months follow-up visit. At 6 months follow-up, though higher mean scores were obtained for bleeding on probing, mucosal thickness in the cylindrical implants group, these differences were not statistically significant (Table 3). Repeated measures ANOVA revealed that there had been significant changes in the parameters of crestal bone loss, bleeding on probing, mucosal thickness during the study period in both the tapered and cylindrical implant groups (Table 4 & Figure 2).

DISCUSSION:

The study results demonstrate that tapered implants had better primary stability and less crestal bone loss as compared to cylindrical implants. While there were no significant differences between these two groups with regard to bleeding on probing and mucosal thickness, crestal bone loss absolute values were found to be slightly inclined in favor of tapered implants. Primary stability is considered as one of the fundamental parameters in the determination of osseointegration. It has been established in the literature that the incidence of implant failure was higher with lesser primary stability values.⁷⁻¹⁰ The rationale for this observation could be found in the reduced micromotion and lesser possibility for fibrous tissue formation at the bone and implant junction among implants with higher primary stability.¹¹ While primary stability does depend on factors outside implant design such as type of bone and the surgical technique used etc.,¹² the methodology adopted in this study with robust exclusion criteria and randomization ensures that the differences in primary stability between the study groups could be attributed to the differences in implant design. The difference in design between the tapered and cylindrical implants which influences the magnitude of surface area available to be in contact with the bone could be one of the primary reasons for increased ISQ values in the tapered implants group. This double-threaded design also allows for smoother penetration and attributes high bone condensing properties. Furthermore, tapered implants exert an increased compressive force on the surrounding bone that allows for thorough clamping of

the bone axially between the threads and the collar. These observations are in congruence with the results from previous literature.¹³⁻¹⁶ However, Waechter J et al.¹⁷ and Sakoh J et al.¹⁸ reported comparable ISQ measurements for tapered and cylindrical implants. The evidence on the influence of implant macro-design on the marginal bone loss around implants is equivocal. Lee et al.¹⁹ reported comparatively lesser marginal bone loss values with tapered implants compared. In the study by Lee et al., the mean difference in the increment of marginal bone loss from baseline to one year between tapered and cylindrical implants was 0.14, with higher increments observed in the cylindrical implants group.¹⁹ Similar observations were made in the present study, with the mean increment in crestal bone loss from baseline to 6 months in the cylindrical implant group being higher compared to the tapered implants group, with a mean difference of 1.6 mm. It could be inferred from these findings that tapered implants fare well in comparison to cylindrical implants demonstrate better integration with the proximal bone. These findings are in accordance with those reported by Kadkhodazadeh et al.²⁰ where the marginal bone loss values at 1-year follow-up were 0.88 ± 0.43 mm and 0.61 ± 0.34 mm for cylindrical and tapered implants, respectively. However, Sargolzaie N et al.²¹ reported comparable crestal bone loss for tapered and cylindrical implants at 6-month follow-up, which is in contrast with the findings of the present study. The present study showed no significant differences in the bleeding on probing and mucosal thickness between the tapered and cylindrical implants, which was in accordance with the

findings reported by Sargolzaie N et al.²¹ and Zafiroopoulos GG et al.²²

CONCLUSION:

Within the limits of this study, it was found that the tapered implants demonstrate better primary stability compared to cylindrical implants. Tapered implants also showed reduced crestal bone loss as compared to cylindrical implants at the follow-up evaluations. However, no significant differences were noted between the two implant designs with regard to soft tissue changes.

A comparative evaluation of mandibular anterior ridge resorption in conventional complete dentures and four implants supported over dentures - An *in vivo* study

Siva Sankar reddy vare¹, T. Krishna Mohan², Ravi Rakesh dev³, Kasu Ramya Krishna reddy⁴, Shabreen Sultana⁵

Department of Prosthodontics, Sibar Institute of Dental Sciences, Takkellapadu, Guntur, Andhra Pradesh, India

ABSTRACT:

Aim: The main goal and purpose of this study was to compare and evaluate the mandibular anterior residual ridge resorption in four implant-supported overdentures and conventional complete dentures. **Methods and Material:** This study involved two groups of 20 patients with different prosthetic constructions. Group (1) mandibular complete dentures (CDs) as a control (10 patients). Group (2) mandibular overdentures supported by four implants placed in the interforaminal region and the first molar region following the two-stage surgical procedure and early loading protocol as a test group (10 patients). Evaluation of anterior residual ridge resorption (RRR) was carried out at baseline, at the time of surgery, and 06 months using CBCT and mucosal thickness was assessed at baseline, three months, and six months. **Statistical analysis:** The data was statistically analysed by using the Mann-Whitney u test. **Results:** The mean change in ridge resorption from baseline to 6 months in the control group is 0.38 ± 0.01 (p-value 0.006). Whereas the mean shift in ridge resorption from baseline to 6 months in the test group was 0.15 ± 0.10 (p-value 0.006). The mean change in mucosal thickness from baseline to 6 months in the control group is 0.54 ± 0.04 (p-value 0.796). Where 0.44 ± 0.05 (p-value 0.796). **Conclusion:** Within the limitations of the study, it was concluded that implant-supported overdentures (ISODs) are an effective treatment modality in the rehabilitation of completely edentulous mandibular arches with improved patient satisfaction, chewing ability and in terms of ridge resorption, mucosal thickness and retention when compared to conventional complete dentures (CDs).

Key-words: Conventional complete dentures (CDs), Implant-supported overdentures (ISODs), Residual ridge resorption (RRR), Cone-beam computed tomography (CBCT).

INTRODUCTION:

The most common treatment for the edentulous patient is conventional dentures. However, such prostheses have well-documented problems such as lack of stability and retention. Continued loss of alveolar bone can occur over time, and cause previously stable dentures to become ill-fitting. It reported that more than 50% of those with complete mandibular dentures might have problems with stability and retention. They are often concerned about denture moving when eating, speaking, or laughing and report fears about the negative effect of dentures on social conditions. In some cases, people avoid social situations altogether¹.

Implant-supported overdentures (ISOD's) offer better stability, retention, and mastication. Patients report

greater satisfaction with aesthetics because the denture is invisible. Implants reduce bone resorption, and the long-term success rate of implants in the lower mandible is 95%, and there are a few complications¹.

The advantage of the overdenture is the increased chewing ability and improved patient confidence. When compared with an implant-supported fixed prosthesis, the overdenture has the advantage of allowing more natural cleaning as they are removable and anchored by a fewer number of implants².

Factors that are affecting the planning of the overdenture treatment are:

- The number and length of the implants
- Quality and quantity of the anchoring bone
- Economic constraints³.

Dr. L. KRISHNA PRASAD
DEAN

In this study, mandibular anterior residual ridge resorption between the conventional complete denture and four implants supported mandibular overdenture was evaluated, and mucosal thickness was also evaluated.

SUBJECTS AND METHODS:

Methodology:

Twenty completely edentulous patients attending the Department of Prosthodontics. All the patients were grouped into two groups.

GROUP 1 (Control Group): 10 completely edentulous patients to be rehabilitated with conventional complete dentures (CDs).

GROUP 2 (Test Group): 10 completely edentulous patients to be rehabilitated with mandibular four implant-supported overdentures (MIODs) placed in the interforaminal region and first molar region.

Subject selection:

Inclusion criteria:

1. Patients (male or female) within the age group of 40-65 years.
2. Absence of any systemic diseases.
3. Completely edentulous maxillary and mandibular arches.
4. Edentulous period of at least three months.
5. Patients should be the first set of denture wearers.
6. Patients with resorbed mandibular ridges, where the amount of resorption occurred, was estimated on OPG by Wical and Swoope method.
7. Adequate interarch space of 16 - 22 mm.
8. Type 1 & 2 bone density
9. Adequate bone height of 15 - 20 mm anteriorly.

Bone width not less than 5 mm, both buccolingually and mesiodistally in the anterior mandible. Posteriorly bone height not less than 12-18 mm and width not less than 8 mm.

Exclusion criteria:

1. A medical and personal history that would complicate the outcome of the study, such as alcohol or drug dependency, poor health, or any other medical, physical, or psychological reason that might affect the surgical procedure, the subsequent prosthodontic treatment and required follow-up.
2. Heavy smokers.
3. Who received bone grafting in the anterior mandible
4. Patients on radiotherapy.
5. Type 3 & 4 bone density.

Two-piece titanium implant system:

ALPHA BIO implants of size, Anterior- 3.3mm diameter, 13mm length Posterior- 4.3mm diameter,

and 8mm length two-piece implants were placed using implant drivers.

Informed consent was taken from all the patients those who were willingly ready for participation.

CONTROL GROUP PATIENTS

In the control group, preoperative CBCT scans were taken for all the patients for evaluation of available length and width of the bone. Initially, primary impressions of patients were brought in stock edentulous using Type I impression compound (figure 1) by muco-compressive technique into which Type II Gypsum product was poured to obtain primary casts (figure 2). Later custom trays were fabricated. An active border moulding technique was carried out in both maxillary & mandibular arches using a low fusing impression compound (Greenstick compound). Later final impressions (figure 3) by mucostatic technique were made using zinc oxide eugenol impression material. These Impressions were filled with type III Gypsum product to obtain master casts (figure 4). Self-cure acrylic denture bases were fabricated using the sprinkle-on method, and occlusal rims were prepared using modelling wax. Orientation jaw relations were performed using earpiece arbitrary type of face bow (Hanau spring bow) and transferred was to a semi-adjustable articulator (Hanau wide-View). Vertical jaw relations were measured using a combination of anatomic, phonetic, and swallowing methods. Bite registration was done by nick & notch method & mounting was done.

The Gothic arch tracings were done to record centric and protrusive movements of the patients (Fig 5). Inter occlusal records (i.e., Centric record-CR, Protrusive record-PR) were made using jet bite occlusal registration Material (Figure 6). These interocclusal records were used for the programming of the articulator (Figure 7). Programming of the articulator was carried out individually for all the patients using the CR and PRs obtained from them. Lateral condylar guidance was calculated using Hanau's formula $L = H/8 + 12$.

Now the tracers were detached, and maxillary & mandibular occlusal rims were reconstructed to their previous original form. Later, teeth arrangements were carried out. To obtain balancing the functional maxillary palatal cusps of posterior teeth were set in the central groove of the mandibular teeth and the maxillary buccal cusps were kept in contact with mandibular buccal cusps. The buccal cusps and palatal cusps were in articulation and functional in the bilateral and protrusive excursions (Figure 8). The try-in of the trial dentures were done and were evaluated for occlusion, aesthetics, and phonetics. After the patient's written approval of the try-in procedure, denture processing was carried out following the conventional method and were lab remounted. Later occlusal corrections were done and were trimmed, finished & polished; followed by denture insertion (Figure 8).

Surgical and prosthodontic protocols:

All the surgical procedures were carried under strict aseptic conditions. Surgery was performed under local anaesthesia. The duplicated denture was used as a radiographic stent (fig 9). Surgical access to the mandible was gained through a mid-crestal incision over the keratinized gingiva with a No.15 B.P. blade. Full-thickness flaps were elevated using a periosteal elevator (fig 10). The osteotomy was carried out following the manufacturer's instructions (fig 11). Starting with a pilot drill of 2mm and sequential drilling under copious irrigation was carried out till the desired dimensions were achieved. Once the osteotomy site was prepared, implants of the selected size were placed using implant drivers and torque wrench (fig 12). The full-thickness flap was closed with 3 -0 silk sutures to achieve primary closure (fig 13). CBCT was taken immediately after surgery to evaluate the placement of implants radiographically and for future reference.

Post surgically, patients have advised medication. After one week, sutures were removed. The patient did not wear the previously constructed, the conventional mandibular denture for the first two weeks. Two weeks after the placement of implants, the impression surface of the denture was relieved at sites corresponding to the implant. The O-ring attachment assembly was placed over the two implants, undercuts blocked out, and auto polymerizing resin was used for direct pickup. The denture was finished, polished, and occlusion was adjusted accordingly.

POSTOPERATIVE RADIOGRAPHIC EVALUATION FOR BOTH

CONTROL AND TEST GROUP PATIENTS FOR BONE LOSS:

Postoperatively, all the patients in the control and test group were radiographically evaluated at baseline, at the time of surgery and six months by CBCT scans. The CBCT scans were taken for each patient at baseline (fig 18), at the time of surgery (fig 19) and six months (fig 20) are evaluated for the amount of anterior mandibular RRR. The method consisted of measurements taken from the upper border of the

anterior crest of the mandible to the lower border of the peak of the mandible regions.

MEASUREMENT OF MUCOSAL THICKNESS:

- Mucosal thickness is assessed using 20 No Endodontic file with a rubber stopper (fig 17). The file was inserted at the predetermined reference point to evaluate the mucosal thickness. The reference points will be taken at the midcrestal point (fig 14) and 5mm below from that point labially (fig 15) and lingually (fig 16) in the mandibular anterior region. The mucosa will be pierced at a 90-degree angle with slight pressure until hard tissue is felt. The distance from the tip of the file and rubber stopper will be recorded using an endo scale at various time intervals, i.e., at baseline, 3 months, 6 months.

DISCUSSION:

Sadowsky (2001)³ stated that bone in the anterior region, i.e., between two mental foramina, was maintained in implant-supported overdenture. The average annual bony residual ridge height physiological shrinkage was about 0.4mm in the

edentulous anterior mandible. Studies had revealed better patient-based results when two implants supported mandibular overdentures have been used compared with conventional lower dentures.

Atwood et al⁴ and Tallgren⁵ showed an average annual alveolar ridge height reduction of

approximately 0.4 mm in the edentulous anterior mandible resulting from physiologic changes. The anterior mandibular ridge under an implant overdenture may resorb as little as 0.5 mm over five years, and long-term resorption may remain at 0.1 mm annually. Following the above study, the present study also evaluated that the mean bone loss at the mandibular anterior region at baseline, at the time of surgery, and six months in four implants supported mandibular overdenture. Mericske-Stern et al⁶ reported 97% implant survival with two implants (splinted or solitary), irrespective of keratinized tissue, or duration of edentulism. In this study also ball type of attachments has been used due to above-said advantages than bar type of attachments. Roynesdal et al. used two titanium-sprayed stable screw implants in the inter foraminal region in a prospective, 24-month study. After three weeks, placement of the overdenture prosthesis to the ball attachments. The implant survival rate was 100%. So, in this present study also, an early loading protocol was followed. Baten burg et al⁷ evaluated mandibular overdenture patients treated with two implants and with four implants. They found no significant differences in the peri-implant health. Following the above study, in this study, four implants supported overdenture had given. In vitro and in vivo studies by Menicucci et al^{8,9} compared the stresses on the bone surrounding two implants with either a bar clip or ball attachments for overdentures. They found higher stresses on the peri-implant bone with a bar clip attachment. It has been shown that solitary ball attachments are less costly; less technique was sensitive and more comfortable to clean than bars. In this study also solitary ball attachments have been used by the advantages showed by the above studies. Gupta A, Rathee S, Agarwal J, Pachar R¹⁰, conducted a study for the presurgical measurement of crestal bone thickness at various implant sites using CBCT images. So, in this study, also cone-beam computed tomography was used to evaluate the preoperative and postoperative bone heights.

PROSTHODONTIC PROTOCOLS

The patient was suggested not to use the conventional dentures for the first two weeks. Two weeks after the placement of implants, the impression surface of the denture was relieved at sites corresponding to the implant. Impression and transfer of the exact positions of the implants to the working cast should be accurate.

Two techniques are commonly used to incorporate the attachment into the denture base. The direct method allows the housings to be inserted intraorally. The indirect technique accomplishes laboratory processing. Common problems with indirect technique may be possible movement and damage to the attachment during packing procedures. Direct pickup technique for the incorporation of housings for ball attachments was used in this study,

as described by Dominici JT et al¹¹. The denture was finished, polished, and inserted.

In an in vivo study, Fontijn-Tekamp et al¹² compared a trans mandibular design of four implants and two anteriorly placed endosseous implants. They found that masticatory forces did not differ between the mainly implant-borne and mucosa-implant-borne treatments.

According to the above study, masticatory forces affecting the mucosal thickness in implant-supported overdenture and conventional complete denture has been assessed. There is no significant statistical difference observed in mucosal thickness assessment.

LIMITATIONS:

The present study was conducted on a sample size of twenty patients within the time-lapse of just six months.

- Evaluation of crestal bone loss with only one of the available systems was considered in the present study.
- The results might vary with other implant systems
- Prospective studies on a more extensive group of patients and long-term evaluation required.

CONCLUSION:

- A decreased ridge resorption in the mandibular anterior region in implant-supported overdenture wearers than conventional complete denture wearers over a while.
- So, it can be advised that implant-supported overdenture is an effective treatment modality in the rehabilitation of completely edentulous mandibular arches with improved patient satisfaction, masticatory capacity, and in terms of ridge resorption and retention.
- Whereas, mucosal thickness did not show much significant difference between both the groups.

ABSTRACT

Aim: The aim of the study is to assess and compare the efficacy of four different disinfectants on adherence of *Candida albicans* to soft denture liner.

Materials and Methods: A total of 55 samples of soft lined acrylic blocks are fabricated and subjected to adherence testing for *Candida albicans*. The samples were then immersed in disinfectant solutions such as Distilled water, 100% Tea tree oil, 100% Neem extract, 2 % Chlorhexidine and 0.5% Sodium hypochlorite. Using the digital colony counter the number of cfu/ml of *Candida albicans* were determined on each sample before and after disinfection.

Statistical Analysis Used: Kruskal Wallis ANOVA and Post hoc tests were performed to analyze pairwise differences between the study groups at each of the dilutions used in this study.

Results: Tea tree oil demonstrate-d highest inhibitory effect on the growth of *Candida albicans* at each of the three dilutions tested. At dilutions 10 and 100, neem extract was observed to be having the next highest inhibitory effect on *Candida albicans* after tea tree oil; however, the efficacy of neem extract reduced with an increase in dilution with chlorhexidine demonstrating the second highest inhibitory effect on *Candida albicans* adherence at 10³ dilution. Posthoc tests were performed to analyze pairwise differences between the study groups at each of the dilutions used in this study. At a dilution of 10, tea tree oil demonstrated significant difference with all other disinfectants except neem extract. At a dilution of 100, similar observations were made with no significant difference in the *Candida* adherence between tea tree oil and neem extract. However, at a dilution of 1000, tea tree oil showed significant difference only with sodium hypochlorite.

Conclusion: It was observed that there exists a significant difference between the disinfectants used in this study on adherence of *Candida albicans* to the soft denture liner.

Keywords: *Candida Albicans*, Soft denture liner, Acrylic blocks, Tea tree oil, Neem extract, Chlorhexidine, Sodium hypochlorite, Colony Counter

Introduction

Denture soft liners distribute the functional load evenly on the denture-bearing area to avoid local stress concentration and improve denture retention by engaging undercuts.

They are primarily used for patients with atrophic ridge, bony undercuts, bruxism, congenital or acquired oral defects, xerostomia, dentures opposing natural teeth, traumatic ulceration.

Soft liners made from silicone or acrylic-based material, both of which may be heat cure or self-cure.^{1,2,3} The favourable properties of them include high bond strength to the denture base, dimensional stability, colour stability, easy application, biocompatibility, and low cost and their disadvantages are loss of softness^{2,3}

Candida albicans is an opportunistic pathogenic yeast. It is usually a commensal organism but can become pathogenic due to local and systemic predisposition caused by chronic irritation or immunocompromised patients. Some natural alternatives have received increased popularity in recent decades.⁴ Efforts to validate their use as therapeutics have come for increasing scrutiny in-vitro and in-vivo. Tea tree oil (TTO) is a volatile essential oil derived mainly from the Australian native plant, *Melaleuca alternifolia*. Tea tree oil is the most active ingredient in many topical formulations used to treat cutaneous infections as it has antimicrobial activity.

The literature documents several reports conducted to evaluate and compare the effectiveness of Chlorhexidine, Sodium hypochlorite, Tea tree oil and Neem extract on adherence of *Candida albicans* to the soft liners. However, till recent day no studies have been conducted to evaluate and compare the effectiveness of Chlorhexidine, Sodium hypochlorite, Tea tree oil and Neem extract on adherence of *Candida albicans* to the soft liners. The present in-vitro study was undertaken to evaluate and compare the antifungal effectiveness of 2% Chlorhexidine, 0.5% Sodium hypochlorite, 100% Tea tree oil and 100% Neem extract on the adherence of *Candida albicans* to soft denture liner.

Materials and methods

An in-vitro study was done in the Department of Prosthodontics and Crown & Bridge, Sibar Institute of Dental Sciences, Takellapadu, Guntur. Metal dies and molds fabricated at Solidworks, Patancheru, Telangana. Adherence testing and colony counting were done in the Department of Microbiology, Vignana University, Guntur.

Standardized aluminium mold preparation: (Figure -1)

Two aluminium blocks of 100 × 70 × 12 mm taken and marked for cutting a mold space of 4×4×2mm and 4×4×4mm. After the markings are done on the block, it is cut using a computerized milling machine into the predetermined dimensions.

Preparation Of Samples:

Total of 55 samples prepared following the below steps.

- Preparation of wax patterns
- Preparation of Poly Methyl Meth Acrylate (PMMA) resin samples
- Packing of the soft liner on resin samples

Preparation of wax patterns:

Fifty-five wax patterns were fabricated by pouring molten modelling wax into the customized mold space of dimensions 4×4×2mm (Figure-2), coated with wax separator for easy retrieval of the wax patterns. The mold with the wax patterns was allowed to solidify in cold water and later retrieved for investment.

Preparation of PMMA resin samples:

Dental plaster was mixed according to the manufacturer instructions and poured into the

base of the dental flask. The wax patterns were invested into the dental plaster to half of their height (Figure-3). After the dental stone set, cold mold seal was applied and is allowed to dry. Dental stone is then mixed and poured into the flask until it is filled to form the second pour. After completing the stone's setting, de-waxing did by immersing the flask in the de-waxing unit at 100°C for 4 minutes. The flask removed from the de-waxing unit, and residual wax was flushed out using hot water (Figure-4).

After the mould is dried, a cold mold seal applied. The heat polymerized resin was mixed in a porcelain jar according to the manufacturer's instructions. The heat-cured acrylic resin packed into the stone mold in the dough stage in both the compartments, and the flask is placed under hydraulic pressure up to 1000 psi. Trail closure also was done, and the flask was removed.

The flasks are again placed back in the hydraulic press, and the resin was allowed to bench cure for 30 minutes. Flask was removed from the hydraulic press and then it was attached to the clamp and placed in a temperature-controlled acrylizer for polymerization. Short curing cycle was followed by putting flask at 74°C for 2 hours, and the temperature was raised to 100 °C and processed for 1 hour. Flask was allowed to cool down to room temperature and then removed from the water bath and deflashed. The heat-cured acrylic specimens were then retrieved carefully, trimmed by using the acrylic trimmer and sandpapered using sandpaper 80 µm, 120 µm, 220µm grit. Finishing and polishing are avoided to simulate the complete denture's intaglio surface.

Packing of the soft liner:

GC SOFT (auto-polymerized acrylic -based-long term) denture liner consists of the two-component system supplied as powder and liquid. The standard powder/liquid ratio is 2.2 g/1.8 g. It was measured into the glass jar and mixed for 30-60 seconds. The mixture was blended to avoid bubbles using a plastic spatula until all of the powder particles were moistened entirely.

The thickness of a soft liner to be packed over the surface of the heat-cured acrylic component was 2 mm (Figure-5). The heat-cured acrylic component was fabricated earlier with similar dimensions of 4mm × 4mm × 2mm (Figure-6) using a standardized aluminium mold. These heat-cured blocks were placed into the aluminium mold of size 4x 4 x 4mm. The bonding surface of the heat-cured acrylic component was dried thoroughly. Then the mixture is packed into mold space above the heat-cured acrylic resin block. The custom-made mould was then covered from the top by a cellophane sheet, and glass slab was pressed firmly against the mold to remove excess material and shape the specimens. Once the material was set, the sample was removed from the mold, placed in water and extra material was trimmed at the periphery using a heated BP blade. In total, 55 GC SOFT liner samples were prepared in the same manner as mentioned above. The samples were stored in a glass container with a lid that contained physiological saline.

Culture of Candida albicans:

Pure Lyophilized culture of *Candida albicans* MTCC 1637 was purchased and inoculated on Yeast Extract Peptone Dextrose growth medium (yeast extract, peptone, dextrose, agar) and incubated at 37°C for 24 hours. Subculture was done on Sabouraud's dextrose agar medium (dextrose, peptone, agar) (Figure-7) by taking 5µl of previous incubated culture growth on YEPD medium using a micropipette. It was then incubated for 48 hours at 37°C and checked for purity. Serial dilution is used in microbiology to estimate the concentration or number of cells/organisms in an incubated plate for a simple counting number of colonies. The culture was taken in a test tube and 9 test tubes, each with 9ml of

sterile diluents, and then at a rate of 0.9% saline.

Serial dilution of 10^{-1} , 10^{-2} , 10^{-3} , 10^{-4} , 10^{-5} , 10^{-6} , 10^{-7} , 10^{-8} , 10^{-9} , dilutions were done by taking 1ml of *Candida albicans* subculture and mixed with 9ml of physiological saline solution. 0.1ml of this solution from each serial dilution was spread on Sabouraud's dextrose agar medium with L shape glass rod to enable candidal growth. These Petri plates incubated at 37 °C for 48 hrs (Figure-8).

After this incubation period, colony counting was done to know the number of candidal colonies before disinfection (Figure-9).

Adherence testing:

A suspension containing 10^6 viable cells per millimetre was prepared in a saline solution using UV-Spectrophotometer at a wavelength of 600 nm, and the absorbance of -0.003 is obtained (Figure-10). Adherence testing was performed in an aseptic environment in a laminar airflow chamber using 24- wells plates for cell culture. For adherence testing, the Sabouraud's dextrose broth 350 µl, 50 µl of *Candida albicans* standardized suspension and one soft-lined acrylic block (sample) added to each well (Figure-11). And the plates were sealed with parafilm and incubated at 37° c for 24 hours.

After the incubation period:

The specimens were washed with 1ml of sterile distilled water and randomly divided equally into five groups according to the disinfecting solution tested.

Group A	Distilled water (control group)
Group B	100 % Tea Tree Oil
Group C	100 % Neem extract
Group D	2 % Chlorhexidine
Group E	0.5 % Sodium Hypochlorite

Disinfection of specimens:

According to the group, the specimens immersed for 10 minutes in 10 ml of the corresponding solution. The samples were then removed, washed with 2ml of sterile distilled water and transferred to test tubes containing 1ml of sterile physiological saline solution. The test tubes were agitated in a vortex stirrer for 60 seconds, and the adhered cells dispersed. (Figure-12)

Colony counting:

For proper colony count, the initial suspension diluted 10, 100, and 1000 times (Figure- 13) in physiological saline solution in the same manner as serial dilution which explained above and 0.1 ml of each suspension plated on growth medium. After 48 hours of incubation at 37°C, the number of colony-forming units per specimen determined using a colony counter (Figure-14). All the media and the armamentarium used for culture autoclaved at temperature 121 ° C for 30 minutes and 15 psi of pressure.

Results

It was observed that there exists a considerable difference between the disinfectants used in this study on adherence of *Candida albicans* to the soft denture liner. Tea tree oil demonstrated the highest inhibitory effect on the growth of *C. albicans* at each of the three

dilutions tested (Table 1). At dilutions 10 and 100, neem extract was observed to be having the next highest inhibitory effect on *C. albicans* after Tea tree oil; however, the efficacy of neem extract reduced with an increase in dilution with chlorhexidine demonstrating the second-highest inhibitory effect on *C. albicans* adherence at 10^3 dilutions. Post hoc tests were performed to analyze pairwise differences between the study groups at each of the dilutions used in this study. At a dilution of 10, tea tree oil demonstrated significant difference with all other disinfectants except neem extract. At a dilution of 100, similar observations were made with no significant difference in the candida adherence between Tea tree oil and neem extract. However, at a dilution of 1000, tea tree oil showed a significant difference only with sodium hypochlorite.

Table 1: - Comparison of efficacy of the disinfectants on adherence of *Candida albicans* to soft denture liner at various dilutions

Dilution	Disinfectant	Mean±SD	Mean rank	P-value
10	Distilled water	47.64 ±58.74	38.23	0.001*
	Tea tree oil	1.91 ± 3.08	13	
	Neem extract	19.73 ±38.82	22.23	
	Chlorhexidine	35.91 ±63.31	32.14	
	Sodium hypochlorite	12.73 ± 8.86	34.41	
100	Distilled water	7.18 ± 11.07	31.95	0.001*
	Tea tree oil	0.27 ± 0.64	13.32	
	Neem extract	2.36 ± 4.41	22.18	
	Chlorhexidine	5.91 ± 9.64	29.32	
	Sodium hypochlorite	12.27 ± 8.34	43.23	
1000	Distilled water	2.73 ± 3.63	27.86	0.016*
	Tea tree oil	0.91 ± 1.57	17.23	
	Neem extract	2.09 ± 1.92	29.23	
	Chlorhexidine	1.82 ± 1.83	25.5	
	Sodium hypochlorite	8.18 ± 10.4	40.18	

Except with Tea tree oil at a dilution of 100, no significant differences were found for distilled water with any other disinfectant at dilutions of 100 and 1000. At a dilution of 10, distilled water showed a significant difference in candidal adherence with Tea tree oil and neem extract.

In intra-group comparisons at various dilutions, only chlorhexidine showed a significant difference in an inhibitory effect on *C. albicans* with a change in dilution. All the other disinfectants did not show significant difference in their inhibition of *C. albicans* with increasing dilution.

Discussion

Pain and difficulty are experienced by many patients using dentures constructed with hard denture bases. On this basis, the resilient materials used to increase resiliency during function and under pressure. Soft lining materials can be defined as soft, resilient, elastic materials which form a cushioned layer between the hard denture base and the oral mucosa.⁵ Denture soft lining materials are broadly divided into two groups of materials. The first group includes the tissue conditioners and temporary soft lining materials typically based on polyethyl methacrylate, an aromatic ester, and ethyl alcohol. The second group comprises permanent soft lining materials based on silicone rubber or acrylic resin. Both of

the groups may be of self-cure (chemically activated) or heat-cure (heat activated).^{6,7,8}

Tissue conditioners or short-term soft liners are uncross-linked, which are formed by polymer chain entanglements. The polymer powder generally consists of poly ethyl methacrylate (PEMA) of molecular weights ranging between 1.79×10^5 and 3.25×10^5 with no initiator^{9,10,11}. The liquid comprises an ester-based plasticizer and 4–50 wt% ethyl alcohol (EtOH) and contains no monomer.^{9,12} Short-term soft liners are tissue conditioners which remain soft for a limited period. It should be replaced with a fresh mix every 2 to 3 days for adequate cushioning.¹³

This study aims to assess the efficacy of various disinfectant solutions on adherence of *Candida albicans* to soft denture liner. According to disinfecting solution tested, samples are divided into group A (distilled water) control group, group B (Tea Tree Oil), group C (Neem Extract), group D (2% Chlorhexidine), group E(0.5%hypochlorite). Each specimen was immersed in 10 ml the corresponding solution for 10 minutes. After immersion, the specimens were removed, washed with 2 ml of sterile distilled water. Then each sample was transferred to test tubes containing 1 ml of clean physiological solution. The tubes were agitated in a vortex shaker for 60 seconds to disperse adhered cells. To get proper colony count the initial suspension was diluted 10, 100 and 1,000 times in physiological solution and 0.1 ml of each suspension was taken and plated on Sabouraud dextrose agar. After 48 hrs. of incubation at 37° C, the numbers of colony-forming units per specimen (CFU/specimen) were determined using a colony counter.

From the results obtained, Table 1 depicts that there exists a significant difference between the disinfectants used in this study on adherence of *Candida albicans* to the soft denture liner. Multiple pairwise comparisons on the effectiveness of the disinfectants on adherence of *Candida albicans* to soft denture liner at multiple dilutions and Intra-group comparison of the efficacy of disinfectants on *Candida* adherence different dilutions. Tea tree oil demonstrated the highest inhibitory effect on the growth of *C. Albicans* at each of the three dilutions tested (Table1). At dilutions 10 and 100, neem extract was observed to be having the following highest inhibitory effect on *C. Albicans* after Tea tree oil; however, the efficacy of neem extract reduced with an increase in dilution with Chlorhexidine demonstrating the second-highest inhibitory effect on *C. Albicans* adherence at 1000 dilution. At a dilution of 10, tea tree oil showed significant difference with all other disinfectants except neem extract. At a dilution of 100, similar observations were made with no significant difference in the candida adherence between Tea tree oil and neem extract. However, at a dilution of 1000, tea tree oil showed a significant difference only with sodium hypochlorite.

The present study's result was congruent with the study conducted by **Pachava K R et al. (2015)**¹⁴. They showed that 15% of Tea Tree Oil had significant antifungal activity against *Candida albicans* on heat-cured acrylic denture base material. **Barua et al. (2017)**¹⁵ reported that the significant benefits of using neem are its easy availability, cost-effectiveness, good shelf life, low toxicity, and no micro-organisms resistance. **Dalwai S et al. (2014)**¹⁶ suggested that Tea tree oil exert a significant antifungal effect (similar to chlorhexidine gluconate 2%). Tea Tree Oil was effective in inhibiting *C. Albicans*.¹⁷ **Iqbal et al. (2016)**¹⁸ stated that Tea tree oil-modified tissue conditioners showed inhibitory and fungicidal activity on *C. Albicans* and effective in treating the denture stomatitis. Sodium hypochlorite was an effective agent in reducing adherent *Candida albicans* both in vitro and in vivo which justifies its application as a cleaning protocol.¹⁹ **R. Sushma et al. (2017)**²⁰ stated that Chlorhexidine has a broad spectrum of activity against various organisms, including *C. Albicans*, the susceptibility of *C. Albicans* biofilms to Chlorhexidine was significantly reduced compared to its action against suspended organisms.

DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

Conclusion

It was thus concluded that there exists a significant difference between the disinfectants used in this study on adherence of *Candida albicans* to the soft denture liner. Tea tree oil demonstrated the highest inhibitory effect on the growth of *C. Albicans*. At a dilution of 10, tea tree oil showed significant difference with all other disinfectants except neem extract. At a dilution of 100, similar observations were made with no significant difference in the candida adherence between Tea tree oil and neem extract. However, at a dilution of 1000, tea tree oil showed a significant difference only with sodium hypochlorite.

Original Research

To determine the Correlation between the occlusal vertical dimension and length of thumb in coastal Andhra population

Siva Sankar reddy vare¹, M. Suresh babu², Ravi Rakesh dev³, S. Asritha⁴

Department of Prosthodontics, Sibar Institute of Dental Sciences, Takkellapadu, Guntur, Andhra Pradesh, India

ABSTRACT:

Aim of the study: To determine the Correlation between the occlusal vertical dimension and length of thumb in coastal Andhra population. **Materials and methods:** The present study was conducted on 220 subjects in coastal Andhra. Occlusal vertical dimension by Niswanger and Thomson method (two pinpoint markings were placed on the tattoo stickers of the tip of the nose and the most prominent point on the chin) was measured, and then the length of thumb finger (The proximal point on the radial side of the proximal crease over the first metacarpophalangeal joint and the distal point in the dactylion, the distal-most part of the thumb) was measured with a vernier calliper. The sample size was measured using G power 3.1.9.2 with α 0.05, Power 80% and the effect is 0.6, and the sample size obtained was 220. **Results:** Pearson correlation test was used to analyze the data. The thumb length was significantly correlated (0.001) with strong and positive values (Pearson's coefficient = 0.662 in the whole population). Regression analysis that thumb length was significantly related to the vertical dimension of occlusion. **Conclusion:** Considering the limitations of the study, the result implies that thumb length can be used as an alternative for establishing O.V.D. in the edentulous patients.

Keywords: Thumb, the vertical dimension of occlusion (O.V.D), Pearson coefficient, edentulous patients.

INTRODUCTION:

The occlusal vertical dimension (O.V.D.) is defined as the distance between two selected anatomic points (usually one point on the tip of the nose and the other on the chin) when in the maximal intercuspal position. It is important for the functional, esthetic, physiological and psychological roles of the patient who loss their teeth and wants rehabilitation.¹

So, the establishment of proper occlusal vertical dimension (O.V.D.) is one of the important tasks for successful prosthodontic therapy.

There are several methods to determine the vertical dimension of occlusion, but each method has its own limitations because they were either tedious, time-consuming, require special instrument/equipment, or expose patients to radiation. So at least 2 or 3 methods should be done on the patient to accurately determine the V.D.O. of that particular patient.

Few studies shows that V.D.O. can be correlated clinically with anthropometric measurements, and

they can simple and precise method for estimating occlusal vertical dimension.² The aim of the study was to evaluate the Correlation between the O.V.D. and the length of the thumb.

MATERIALS & METHODS:

(a) SOURCE OF DATA:

The present study will be conducted on 220 subjects in coastal Andhra Pradesh.

(b) STUDY DESIGN:

Occlusal vertical dimension was measured by Niswanger and Thomson method (two pinpoint markings were placed on the tattoo piece on tip of the nose and the most prominent point on the chin) and then the length of thumb finger (The proximal point on the radial side of the proximal crease over the first metacarpophalangeal joint and the distal point in the

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

dactylion, the distal-most part of the thumb) was measured.

- Attrition
- Trauma

(c) METHOD OF COLLECTION OF DATA:

The patients are selected according to the following criteria

Inclusion criteria: subjects with

- Full natural dentition (third molar not taken into account)
- Straight profile on visual examination

Exclusion criteria: Any history

- Orthodontic/surgical treatment,
- Presence of large carious lesions
- Abnormality or absence of thumb/s
- Hormonal abnormalities (e.g., gigantism, acromegaly)
- Open bite or deep bite cases
- Teeth anomalies

EVALUATION CRITERIA:

CLINICAL PARAMETERS:

- Occlusal vertical dimension was measured by Niswanger and Thomson method (two pinpoint markings were placed on the tattoo piece on the tip of the nose and the most prominent point on the chin)
- Length of thumb (The proximal point on the radial side of the proximal crease over the first metacarpophalangeal joint and the distal point in the dactylion, the distal-most part of the thumb)

Potential Risks and Benefits:

NIL

STUDY FLOW CHART

For occlusal vertical dimension-

Subjects should be seated comfortably in the dental chair in a fully upright position.

A head-rest was used to support the head with the camper's line of the subject in a horizontal position.

The subject was made to occlude the total teeth in maximum intercuspation.

Then two markings were placed on the tattoo marks on tip of the nose and the most prominent point on the chin, and the distance between them was measured with a vernier calliper.

For length of the thumb-

Each subject should be asked to place his or her hand on a graph paper keeping the fingers separated and the thumb placed comfortably

The proximal point of first meta carpophalangeal joint and the distal point in the dactylion, the distal-most part of the thumb, were to be marked.

The ends of the calliper were to be placed over these two landmarks, and the distance between them gives the maximum length of thumb

Data will be analysing using using G power 3.1.9.2 software.

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

PROCEDURE:

Each volunteer was asked to place his or her hand on a graph paper with the palm facing downward and the fingers separated and the thumb placed comfortably. A sliding caliper was used to calculate the length of the thumb (Figure 1), as in the method used by Kumar et al. The proximal point on the radial side of the proximal crease over the first metacarpophalangeal joint and the distal point in the dactylion, the distal-most part of the thumb, were marked.

Figure 1: Measurement of thumb length.

The ends of the caliper were placed over those two landmarks of the subject, and the length between them measured the maximum length of thumb.

To measure the O.V.D., routinely used methods in the Department of Prosthodontics, Sibar Institute of Dental Sciences were employed (Figure 2). The subject was positioned comfortably in the dental chair in a fully upright position. A headrest was used to give support the head with the camper’s line of the

subject in a horizontal position. The subject was made to occlude the teeth in maximum intercuspation. Then two markings were placed on the tattoo points of tip of the nose and the most prominent point on the chin. The distance between them was calculated with a sliding caliper.

Figure 2: Measurement of O.V.D. with modified Vernier caliper

RESULTS:

The study was conducted among 220 students of the College of Sibar Dental Surgery. Pearson correlation test was used to analyze the data. The mean O.V.D. of the population was 5.58682 mm, and the mean thumb length (T.L.) of the studied population was 6.03000 mm(fig-3). The thumb length was significantly correlated (0.001) with strong and positive values (Pearson’s coefficient =0.662 in the whole population) (Fig-4). The graph shows the mean and range of various measurements (Fig-5)

Descriptive Statistics

Figure 5: Range of variations in vertical dimension and thumb length

DISCUSSION:

The edentulism results in poor appearance of the lower third of the face. The rehabilitation of correct vertical dimension in those who have lost it should be in harmony with the upper part of the face. Prosthodontists have long been searching for universally accepted method of determining the O.V.D. There were methods like use of anterior teeth measurements⁷, closest speaking space⁸, swallowing method⁹, patient’s neuromuscular perception¹⁰, cephalometric radiographs^{11,12}, intra-oral and extra-oral anatomic landmarks¹³ and measurement of fingers⁶. All of these methods have disadvantages. Some methods have errors in measurement, while others are leads to difficult application, higher amount of cost, or longer time period for application. Any change in determining O.V.D. can be detrimental to the esthetics of facial soft tissues, causes difficulties in phonation, and leads to temporomandibular joint dysfunction.

Pre-extraction record is always superior to these methods. But recording the O.V.D. of all patients is not always possible¹⁵. A pre-extraction records, knowledge of aesthetics, relationship of teeth to the ridges, measurements relative to the lip length, use of phonetics and other methods are employed. This study was taken to investigate the relationship between the O.V.D. and the length of the thumb. The present study gave some idea about the relation between the facial measurement and length of the thumb their use in determining occlusal vertical dimension. The studies between the length of the thumb to the length of the lower facial height can help the clinician to establish the correct O.V.D. in the treatment of patients requiring restorations like the complete denture.

Geerts et al¹⁴ evaluate the correctness of the chin–nose distance measurement. The compressibility of skin cannot be avoided, so there may be some degrees of errors in measurement. Measurement by modified callipers invariably leads to some differences in the different studies. The present study did not compare these procedures of measuring the O.V.D.

LIMITATIONS:

The limitations of this study were errors occurred while measuring dimensions in big sample, and only one ethnic group are considered in the present study, so the findings cannot be extrapolated to other ethnic groups or races.

CONCLUSION:

Correlation of the length of the thumb to the O.V.D. was statistically significant. The Correlation between the length of the thumb and vertical dimension of occlusion was positive and strong in the total population. Within the limitations of this present study, the final result shows that thumb length can be used as an alternative for establishing O.V.D. in the edentulous patients.

ABSTRACT

Introduction: Provisional restorations are an integral part of fixed prosthesis and dental implantology. They serve as a key role in functional and esthetic tryin for design of final prosthesis. Fixed prosthesis prognosis depends on the quality of provisional restoration. In long term cases like full mouth rehabilitation and in implant supported prosthesis flexural strength (FS) and elastic modulus (EM) of the interim prosthesis play a vital role.

Aim: To evaluate and compare the flexural strength (FS) and elastic modulus (EM) of provisional crown and bridge materials stored at different time intervals in artificial saliva.

Materials And Methods: Ninety bar-shaped specimens (with dimensions of $25 \times 2 \times 2$ mm) as per American National Standards Institute (ANSI specification no 27) were fabricated with three provisional restorative materials Polymethyl Methacrylate (PMMA), Bis acrylic, Urethane dimethacrylate (UDMA) and are stored in artificial saliva at different time intervals. Further three point bending test were carried out in universal testing machine to calculate FS and EM. Changes were evaluated and data was analysed using one way ANOVA and paired t test.

Results: Results showed significant difference ($P < 0.05$) in FS values of provisional materials at different storage intervals except PMMA showed non-significant difference ($p > 0.05$) between 10days to 30days storage. There was non-significant difference ($p > 0.05$) of EM of bis-acryl samples between 24hrs to 10days and from 10days to 30days of storage.

Conclusion: Within the limitations of the study, it can be concluded that the FS and EM of Bis acrylic is comparatively better than PMMA and UDMA. Bis acrylic could be a better provisional restorative material for an extended period as less change was observed in elastic modulus of bis-acryl during long term storage compared to other materials.

KEYWORDS

Flexural strength, elastic modulus, Provisional restoration, Polymethyl methacrylate (PMMA), Bis-acrylic, Urethane dimethacrylate (UDMA).

INTRODUCTION

In fixed prosthodontic treatment it is important to protect the prepared teeth with provisional restoration so that the patient can be made comfortable during cast restoration fabrication¹. Materials providing more durability are required in situations like provisional FDPs that are expected to function for extended periods of time or when additional therapy is required before completion of definitive treatment as in case of prosthetic phase of dental implants where tissue contour issues should be solved and longer treatment duration as in full mouth rehabilitation.²

For longevity of a provisional restoration understanding its mechanical properties is necessary. Among mechanical properties, the flexural strength and elastic modulus of the interim prosthesis are important, particularly if the patient is expected to wear the restoration for a long period of time (e.g. full mouth rehabilitation)³. Flexural strength also known as transverse strength, is a measurement of the strength of a bar (supported at each end) under a static load. Elastic modulus describes the relative stiffness or rigidity of a material⁴.

The present study was carried out to evaluate and compare the flexural strength and elastic modulus of three provisional crown and bridge materials at different storage intervals in artificial saliva for 24hrs, 10 days and 30 days after setting.

MATERIALS AND METHODOLOGY

Following provisional crown Materials were used in this study

Table 1: Provisional Crown Materials

Product Name	Manufacturing Company	Lot no.
DPI (self-cure tooth moulding powder)	Dental Products of India, Mumbai, India	3452
REVOTEC LC (light cure resin for temporary crown, bridge, inlay & onlay)	GC Corporation., Tokyo, Japan.	1806061
TRANTEMP (bis-acrylic composite)	Nexobio co.ltd, Chungcheongbuk-do Korea.	80529

Metal mold consists of central metal plate and surrounding metal casing. Central metal plate has 5 slots of dimensions $25 \times 2 \times 2$ mm (**Figure 1**) in to which material was dispensed to get specimens of similar dimensions based on American National Standards Institute (ANSI) specification no 27 and surrounding metal casing which prevents movement of central metal plate that was split in between the slots for easy retrieval of samples.

Figure 1: Master Metal Mould

A total of 90 samples are included in this study and they are divided into 3 groups based on material used for fabrication. Each group is further divided in to 3 sub groups based on duration of immersion in artificial saliva i.e., 24hrs, 10days and 30days. (**Figure 2**)

All samples were fabricated using a split machined aluminum mold, sandwiched between two glass slabs. Bis-acrylic composite (Trantemp) was manipulated using automix cartridge loaded by an automix dispensing gun (1:10). The mixing tip of the cartridge was held at one end of the mould and material was expressed into the mould

moving the automix dispenser slowly to the other end to avoid incorporation of air bubbles. Light cure composite resin (Revotek LC putty stick) material was kneaded gently with fingers to soften it, dispensed and packed into the mould avoiding air bubbles or defects and glass slab is placed over mould. Care was taken to prevent over kneading of the material. Dispensed material was light cured according to the manufacturer's instructions i.e for 20secs. A required amount of the DPI Self Cure powder and liquid were measured in the ratio of 2:1 by volume, respectively and dispensed in a dappen dish. The polymer-monomer was mixed to a homogenous consistency using a stainless steel mixing spatula. The paste was then filled into a 2 cc disposable syringe and dispensed into the mould avoiding air bubbles. The specimens were subjected for testing under universal testing machine (DAK system Inc Series 9000) which uses 3 point bending test. The specimens were kept on the supports which are 20mm apart from each other. The cross head speed of this machine head is 0.5mm/min. Each specimen was gradually loaded and the point where it flexes and breaks were noted. (Figure 3)

Figure 2: Samples In Artificial Saliva

Figure 3: Testing Of Samples Under Universal Testing Machine

The flexural strength (S) and the elastic modulus (E) were calculated using the following formula for each sample:

Flexural strength (FS)
 $S = 3PL/2wt^2$

Elastic modulus (EM)

$E = PL^3 / 4wt^3\delta$ where

- P- Applied load (N)
- w- width of sample(m)
- t- Thickness of sample(m)
- L- span
- δ - Deflection

The values of each group were tabulated and statistically analyzed using ANOVA one way test and Paired t test.

RESULTS

The mean flexural strength and elastic modulus of all specimens are tabulated. Intra group comparison of Flexural strengths of PMMA, bis-acrylic and UDMA is done. In group-A there was significant difference (P<0.05S) in FS between 24 hr sample to 10days sample and non-significant difference(P>0.05) between 10days to 30days sample. In group-B there was non-significant difference (p>0.05) in FS between 24 hr sample to 10days sample and significant difference (P<0.05 S) between 10days to 30days sample. In group-C there was

significant difference (P<0.05 S) in FS between 24 hr sample to 10days sample and between 10days to 30days sample.

Intra group comparison of elastic modulus of PMMA, bis-acrylic and UDMA is done. In group-A there was significant difference (P<0.05 S) in EM between 24 hr sample to 10days sample and non-significant difference (p>0.05) between 10days to 30days sample. In group-B there was non-significant (p>0.05) difference in EM between 24 hr sample to 10days sample and between 10days to 30days sample. In group-C there was significant difference in FS between 24 hr sample to 10days sample (P<0.05 S) and 10days to 30days sample.

DISCUSSION

Autopolymerizing polymethyl methacrylate is the most commonly used material for fabrication of interim restorations but its use is on decline because of their disadvantages like polymerization shrinkage,

exothermic setting reaction, and the irritation associated with monomer and inaccurate marginal adaptation.⁵

Bis-acrylic composite based provisional restorative materials are gaining popularity because of their cartridge delivery system. This dispensary method is not only convenient but also may allow for a more accurate and consistent mix and thereby improving its physical and mechanical properties. Bis-acryl composite resins have low polymerization shrinkage, low exothermic response but this material has disadvantage of being costly and their repair is troublesome.⁶

The visible Light polymerized (VLC) material containing urethane dimethacrylate, a resin whose polymerization is catalyzed by visible light and initiated by camphoroquinone. UDMA usually incorporate filler such as microfine silica to improve physical properties like reduced polymerization shrinkage. Light-cured urethane dimethacrylates have an advantage of controllable working time, great wear resistance, low temperature changes. Their hindrances are poor peripheral fit, weak nature and high cost.⁷

Results in this study showed that flexural strength and elastic modulus of PMMA decreases from 24 hrs storage (subgroup IA) to 10 days storage (subgroup IB) in artificial saliva. There was no significant change in FS and EM from 10days storage to 30days storage which may be due to saturation.

Results in this study showed that flexural strength of Bis-acryl provisional material increases from 24 hr storage (subgroup IA) to 10 days of storage (subgroup IB) in artificial saliva. The reason may be the increasing conversion of reactive double bonds by radicals and, on the other hand, relaxation phenomena within the polymer network.⁸ There was slight decrease of FS from 10 days to 30days storage which can be due to leaching of filler content. There was no significant change in elastic modulus from 24hr storage to 10days storage and 10days storage to 30 days storage. Bis-acryl has a rigid central structure.⁹

Results in this study showed that flexural strength of UDMA decreases from 24 hr storage to 10 days storage and from 10days to 30days storage in artificial saliva. Glass fillers are slowly leached out in the presence of saliva, thus reducing the mechanical properties of the interim composites. Elastic modulus is less for UDMA as there are no phenol rings in its monomer when compared to Bis-acryl hence it has higher flexibility.¹⁰

Determination of flexural strength was unproblematic for composite based materials as all specimens broke after exceeding a certain stress maximum. In contrast, most specimens made of polymethylmethacrylate (group I) and UDMA (Group III) did not break but were distorted instead. Consequently, the results for group I and group II have to be interpreted with care. The lack of fracture can be related to the chemical nature of resins. The main monomer component of poly methylmethacrylate forming the matrix is methylmethacrylate which forms linear polymer chains without any cross-links. A similar phenomenon was observed by Lang et al who investigated the fracture resistance of provisional crown and bridge materials in artificial oral environment¹¹.

The results obtained in this study were in correlation with the study conducted by S Dagar et al on direct and indirect provisional materials and found that Protemp 2 has lesser flexural strength as compared to heat cure polymethyl methacrylate but more than self cure poly methyl methacrylate.¹² According to the results of the study among all groups flexural strength and elastic modulus of bis- acryl is highest when compared to other groups after 24hr storage in artificial saliva.

The mean values of flexural strength of Group I and Group II were similar with the results obtained in the study conducted by Haselton et al who compared the flexural strength of five auto-polymerising methacrylate-based resins and eight bis-acryl resins. The authors reported that most of the bis-acryl resins demonstrated significantly superior flexural strength over traditional auto-polymerizing methacrylate resins.¹³

The results obtained in this study were contradictory with the study conducted by Koumjian and Nimmo who tested 3 methyl methacrylate resins and an earlier generation bis-acryl resin. They evaluated the flexural strength immediately following polymerization, seven days of dry storage and 7 days of wet storage. They found that water storage

absorption resulted in a slight but insignificant decrease in the transverse strength of methyl methacrylate and bis acryl. Transverse strength varied widely in the repaired group, and all materials showed a statistically significant reduction compared with the seven day wet storage group. Although no data is available to compare the type of resin matrix or filler content of those bis-acryl materials, it is evident that the difference in flexural strength performance was material-specific.¹⁴

The results obtained in this study for Group I and Group II were in correlation with the study by Balkenhol et al who evaluated the flexural strength and elastic modulus of interim resin materials at different storage times and concluded that the mechanical properties of composite resin-based materials are superior to methacrylate resins and recommended a dual-curing interim resin material if a high mechanical strength is indispensable directly after fabrication. They explained that in dual-curing materials a large amount of polymerization takes place at the beginning because of the light curing initiation of the reaction.¹⁵

The results obtained in this study for group III were in correlation with the study done by Ireland & Dixon where the elastic moduli and moduli of rupture of Proviopont DC resin, Triad (autopolymerising poly methyl methacrylate) and a 50:50 mixture of jet acrylic resin and orthodontic resin was evaluated. Proviopont DC resin (dual-polymerizing resin) exhibited significantly higher elastic moduli and moduli of rupture values at the 24 hour test time. However, Proviopont DC resin exhibited the greatest decrease in these values over time. This result was explained by the fact that a large amount of polymerization takes place at the beginning for this provisional crown and bridge material caused by the light curing initiation of the polymerisation reaction.¹⁶

Limitations Of The Study

This in-vitro study evaluated flexural strength and elastic modulus of three provisional restorative crown and bridge materials.

1. In the oral cavity, the provisional restoration is exposed to forces of varying magnitudes acting in different directions, and there are also temperature variations. The same situation was not simulated in this in vitro study.
2. Provisional restorations are subjected to force immediately after fabrication but in this in vitro study samples are subjected to load after soaking in artificial saliva for 24hrs and 10 days. Therefore further investigations are required under more closely simulated clinical conditions.

CONCLUSION

Bis-acryl interim materials exhibited higher flexural strength than the polymethacrylate resins and urethane dimethacrylate provisional materials. Polymethylmethacrylate and urethane dimethacrylate had shown more deflection than bisacrylate. They have undergone more plastic deformation before breakage therefore Elastic modulus of polymethylmethacrylate and urethane dimethacrylate is less when compared to bis-acryl composite provisional material.

Abstract

Background:

In this study, we determined the effect of bone density on implant stability.

Methodology:

Two hundred and sixty dental implant sites in 128 patients were assessed for resonance frequency analysis (RFA) following implant insertion, at 6 months and 12 months. The implant stability quotient (ISQ) was determined.

Results:

The mean \pm standard deviation bone density in anterior mandible was 862.8 ± 203.4 Hounsfield units (HU), in posterior mandible was 528.4 ± 115.6 HU, in anterior maxilla was 594.2 ± 95.2 HU, and in posterior maxilla was 438.1 ± 110.2 HU. The mean insertion torque in successful implants was 38.2 ± 7.1 Ncm and in failed implants was 22.4 ± 4.2 Ncm. The mean RFA value in successful implants was 65.4 ± 5.8 and in failed implants was 45.8 ± 4.1 ISQ. A statistically significant ($P < 0.05$) difference was obtained.

Conclusion:

Within the limitation of the study, we observed that successful implants exhibited higher RFA and insertion torque and were higher into failed implants suggesting a correlation of bone quality and implant stability parameters.

KEYWORDS: *Implant stability quotient, insertion torque, resonance frequency analysis*

INTRODUCTION

Dental implants have been widely used for the correction of missing few or multiple teeth have become popular in the last couple of years owing to several benefits. The higher survival rate and limited surgical intervention have led treatment of choice among dentists and patients.[1] Although it has significant higher success rate, numerous factors affect its survival rate. These are procedure-related and patient-related factors. The quantity, i.e., amount of bone present and quality, i.e., type of bone present determines the process of osseointegration. Type of dental implant used as well as the surgical method adopted is procedure-related factors.[2]

According to Misch bone density classification, Type D1 has higher survival rate which is usually found in mandibular anterior region. Type D2 is seen in the mandibular posterior region, Type D3 in maxillary anterior region and Type D4 poorest of all is encountered in maxillary posterior teeth region. Type D1 is strongest of all with 80% stronger trabeculae, Type D2 has combination of dense and porous bone with 40%–60% stronger trabeculae than Type D3 with 50% weaker trabeculae than D2, and Type D4 has poor density with trabeculae strength 10 times weaker than Type D1.[3]

Dental implant stability is the deciding parameter which ensures success rate of dental implant. Insertion torque, periotest, and resonance frequency analysis (RFA) are way of checking dental implant stability. The insertion torque method measures the quantity of torque required to insert the implant in the bone.[4] Periotest calculates the degree of the periodontal integration of teeth and the stiffness of the bone/implant interface. RFA calculates the bone/implant interface stiffness using Osstell instrument.[5] We assessed the effect of bone density on implant stability.

METHODOLOGY

This study consisted of 260 dental implant sites in 128 patients of both genders conducted in the prosthodontics department. All enrolled patients were made aware of the study and their written consent was taken. Ethical clearance for the study was obtained before starting the study.

Data pertaining to all patients such as name, age, and gender were recorded. A thorough oral screening was done followed by computed tomography of the recipient implant site taken with Siemens Germany operating at standardized operating parameters (potential difference - 120 kVp, 90 mA tube current, 1 mm slice thickness, and slice intervals). The mean bone density of the potential

implant site was measured using software Siemens. The bone density was measured in Hounsfield units (HU).

Dental implants were inserted following all standardized surgical procedures. RFA was performed with an Osstell instrument following implant insertion, at 6 months and 12 months. RF values were recorded in terms of implant stability quotient (ISQ). High ISQ value (100) is showing high stability and low implant stability was given to lower number (1). The maximum insertion torque value was recorded with OsseoCare motor during implant placement [Figures 1–4]. A successful implant showed no pain, suppuration and any pathologic processes, no evidence of periapical implant radiolucency, sufficient implant stability, the implant provided attachment to prosthetic part based on criteria proposed by Lekholm and Zarb.[6] The results of the study were subjected to statistically analyzed with 0.05 level of set as significant.

DISCUSSION

Bone density is indispensable for the dental surgeon to arrive at the best treatment strategy and to finalize suitable implant design to achieve primary stability.[7] The advancement of designing in implants, surface treatments, and study of bone architecture proved beneficial in the field of implantology. The implant stability is the principal prerequisite to establish the prosthetic management that shall be initiated, which needs to be assessed before force insertion.[8] The present study was conducted to determine the effect of bone density on implant stability.

In the present study, males were 72 in number having 140 dental implants and females were 56 in number having 120 dental implants. Male had eight and female had seven failed implants. Turkyilmaz and McGlumphy[5] in their study on 300 implants in 111 patients determined effect of bone density on implant stability. Results showed mean bone density (620 ± 251 HU), insertion torque (36.1 ± 8 Ncm), and RFA value (65.7 ± 9 ISQ) at implant placement. There was significant correlation between insertion torque and bone density, ISQ values and bone density, and ISQ values and insertion torque, and bone density was observed. The mean bone density, insertion torque, and RFA at implant insertion area was 645 ± 240 HU, 37.2 ± 7 Ncm, and 67.1 ± 7 ISQ, respectively, and in 20 failed implants was 267 ± 47 HU, 21.8 ± 4 Ncm, and 46.5 ± 4 ISQ, respectively, with statistically significant differences ($P < 0.001$).

We found that mean \pm SD bone density in anterior mandible was 862.8 ± 203.4 HU, in posterior mandible was 528.4 ± 115.6 HU, in anterior maxilla was 594.2

± 95.2 HU, and in posterior maxilla was 438.1 ± 110.2 HU. Oliscovicz *et al.*[9] in their study used 32 Conexão® implants, eight conical, and 24 cylindrical. All were placed in Nacional® polyurethane using 15, 20, and 40 PCF densities. Results exhibited the best performance was the interaction implant CA x 40PCF substrate with difference from the other implants inserted in all substrates.

We found that the mean insertion torque in successful implants was 38.2 ± 7.1 Ncm and in failed implants was 22.4 ± 4.2 Ncm. The mean RFA value in successful implants was 65.4 ± 5.8 and in failed implants was 45.8 ± 4.1 ISQ. Cornellini *et al.*[10] inserted 40 implants in 20 patients, the mean ISQ values were 72 at implant surgery and 74.5 after 1 year, which was not statistically significant ($P > 0.05$).

We observed that mean ISQ value in the anterior mandible was 72.1, 71.4, and 73.6 at the time of surgery, at 6 months and 1 year, respectively. In posterior mandible was 67.4, 66.7, and 69.7 at surgery, at 6 months and 1 year, respectively. In the anterior maxilla at surgery, at 6 months and 1 year was 68.4, 69.2, and 70.1, respectively. In the posterior maxilla was 57.6, 58.2, and 59.6 at surgery, at 6 months and 1 year, respectively. Sjostrom *et al.*[11] studied 192 implants after bone-graft healing. Results showed that the ISQ value was 60.2 ± 7.3 at insertion time and 62.5 ± 5.5 after 6 months of prosthetic part insertion having significant difference between both periods. A ISQ of 61.9 ± 9.5 and 60.2 ± 7.3 was observed between implant insertion and abutment attachment with nonsignificant difference. A ISQ value of 62.5 ± 5.5 and 61.8 ± 5.5 was found at 6 months and 3 years of bridge loading, respectively.

The shortcoming of the study is small sample size and short follow-up.

CONCLUSION

Authors found that insertion torque and RFA was higher in successful implants as compared to failed implants suggesting correlation of bone quality and implant stability parameters.

ABSTRACT

Introduction: In this study we evaluated the quality of life with obturators in patients post maxillectomies

Materials and Methods: Thirty-six subjects were enrolled with maxillary defects, irrespective of the cause, planned for definite obturator prosthesis, were recruited. Head and Neck version 1 of Quality of Life Questionnaire was used before surgical intervention and one month after definitive obturator. Questionnaire includes 35 questions related to the patient's physical health, well being, psychological status, social relation and environmental conditions. The data were processed with statistical package for social science (SPSS). Probability level of $P < .05$ was considered statistically significant.

Results: The quality of life after rehabilitation with obturator prosthesis was 81.48% (± 13.64) on average. On item-level, maximum mean scores were obtained for items problem with teeth (1.87 ± 0.94), pain in mouth (1.80 ± 0.92), trouble in eating (1.70 ± 0.88), trouble in talking to other people (1.60 ± 1.22), problems in swallowing solid food (1.57 ± 1.22) and bothering appearance (1.53 ± 1.04); while minimum scores were obtained for the items coughing (1.17 ± 0.38), hoarseness of voice (1.17 ± 0.53), painful throat (1.13 ± 0.43), trouble in having social contacts with friends (1.10 ± 0.40) and trouble having physical contacts with family or friends (1.10 ± 0.31).

Conclusion: Obturator prosthesis is a highly positive and non-invasive approach to improve the quality of life of patients with maxillectomy defects.

Key Words: Quality of life; Maxillectomy; Obturator prosthesis; Oral cancer

I. INTRODUCTION

Presently, the multitudinal impact of maxillofacial tumors on a patient's life has been recognized, which led various researchers to investigate the quality of life of those patients. However, studies evaluating the quality of life of patients with maxillectomy defects and the effect of prosthodontic therapy with obturator prostheses on their quality of life remain rare.

The significant areas of treatment concern after maxillary resection are reconstruction of the defect and restoration of oronasal functions while maintaining the facial contours. The obturator prosthesis fulfills most of these requirements and it also reduces the procedure time and offers the possibility of immediate rehabilitation. It is possible to examine the surgical site after removing the prosthesis, and recurrence may be detected at an early stage.⁵⁻⁸ So, the obturator can be considered as a highly positive approach for rehabilitation after maxillectomy. However, in some cases, impaired obturator functioning and handling may lead to deficits in speech, mastication, swallowing or facial disfigurement, thereby resulting in patient dissatisfaction.¹⁻¹⁰

Various investigators have found that orofacial deformities result in profound psychological and social consequences.¹¹⁻¹³ Such subjects are more likely to encounter social negligence and usually develop negative personality traits. Maxillo- facial injury rehabilitation represents one of the greatest challenges to public health service providers worldwide because of their high incidence and significant financial burden. They are often associated with morbidity and varying degree of physical, functional and aesthetic damages.^{12,13}

Hence, in this study we evaluated the quality of life with obturators in patients post maxillectomies.

II. MATERIALS AND METHODS

Thirty six subjects were enrolled in the study for the span of sixteen months. Ethical approval was obtained from the institution.

The instructions regarding filling of questionnaire were explained to the selected thirty six subjects, but for evaluation, only thirty subjects were available as six subjects had declined to be involved in the study. The Hindi version of European Organization for Research and Treatment of Cancer, Head and Neck version 1 of Quality of Life Questionnaire (EORTC QLQ-H &N 35) was used.

The questionnaire includes 35 questions related to patient's physical health, well being, psychological status, social relation and environmental conditions. The questionnaire was divided into two parts with initial 30 multiple choice questions, with scoring based on Likert scale of four-points, which were used to quantitatively measure the patient's perceived changes in the quality of life. Remaining 5 questions were dichotomous and were used for status evaluation of the patients. Patients were asked to complete questionnaire based on their experience during the past one week before surgical intervention, the same questionnaire was completed by the patient after definitive prosthetic rehabilitation. The quality of life of subjects was broadly divided into eight dimensions as follows:

Item Nos. 1-4 Pain

Item Nos. 5-8 Swallowing

Item Nos. 9-12 Teeth and Mouth Item Nos. 13-14, 22 Senses

Item Nos. 15-17 General Health Item Nos. 19-21 Eating

Item Nos. 18, 23-28 Social Item Nos. 29-30 Sex

The probability levels of $P < .05$ were considered statistically significant for all statistical analyses.

III. RESULTS

The patient's perceived quality of life after rehabilitation with obturator was calculated to be 81.48% (± 13.64). Majority of patients belonged to age group <30 years and age group 51-60 years respectively, showing a bimodal age distribution. There were only 2 patients in age group >70 years. Mean age of patients was 46.83 ± 16.98 years.

Squamous cell carcinoma was the most common clinical diagnosis (50%) responsible for maxillectomy. Surgery alone ($n = 19$; 63.3%) was the most common treatment modality used.

On item-level, maximum mean scores were obtained for items problem with teeth (1.87 ± 0.94), pain in mouth (1.80 ± 0.92), trouble in eating (1.70 ± 0.88), trouble in talking to other people (1.60 ± 1.22), problems in

swallowing solid food (1.57 ± 1.22) and bothering appearance (1.53 ± 1.04) while minimum scores were obtained for the items coughing (1.17 ± 0.38), hoarseness (1.17 ± 0.53), painful throat (1.13 ± 0.43), trouble in having social contacts with friends (1.10 ± 0.40) and trouble having physical contacts with family or friends (1.10 ± 0.31) (Table 1).

Minimum effect on quality of life was observed for the sex related QOL whereas maximum was observed for social life. At item-level, statistically significant reduction in mean scores was found for the items such as pain in mouth ($P=.032$), soreness in mouth ($P=.001$) and coughing ($P=.025$) (Table 1). A statistically significant increase in mean scores was observed for items such as problems in swallowing solid food, problem in opening mouth wide, trouble in eating, difficulty in eating food in front of family and other people, problem in enjoying food, difficulty in conversation to people and on the telephone, problem in making social contacts with friends, trouble in making public appearance and difficulty in making physical contacts with others. For all the other items the change was not significant statistically ($P>.05$). Overall, no significant change in mean scores was observed.

Table 1. Comparison of pre-treatment and post-treatment quality of life scores

	Mean	SD	Mean	SD	t	P
1. Pain in mouth	1.80	0.92	1.33	0.84	2.249	.032
2. Pain in jaw	1.50	0.97	1.13	0.35	2.009	.054
3. Soreness in mouth	1.40	0.62	1.00	0.00	3.525	.001
4. Painful throat	1.13	0.43	1.00	0.00	1.682	.103
5. Problem in swallowing liquids	1.27	0.74	1.53	0.97	-1.439	.161
6. Problem in swallowing pureed foods	1.23	0.63	1.27	0.52	-0.571	.573
7. Problems in swallowing solid food	1.57	0.90	2.03	0.89	-3.500	.002
8. Choking while swallowing	1.20	0.61	1.17	0.59	1.000	.326
9. Problem with teeth	1.87	0.94	1.90	0.76	-0.254	.801
10. Problem in opening mouth wide	1.47	0.78	2.10	0.76	-5.641	.000
11. Dry mouth	1.37	0.76	1.47	0.73	-0.902	.375
12. Sticky saliva	1.33	0.66	1.33	0.71	0.000	1.000
13. Problem with sense of smell	1.47	0.97	1.33	0.55	0.750	.459
14. Problem with sense of taste	1.20	0.48	1.23	0.43	-0.328	.745
15. Coughing	1.17	0.38	1.00	0.00	2.408	.023
16. Hoarseness	1.17	0.53	1.07	0.25	0.902	.375
17. Feeling of illness	1.37	0.67	1.23	0.43	1.072	.293
18. Bothering appearance	1.53	1.04	1.60	0.62	-0.441	.662
19. Trouble in eating	1.70	0.88	2.37	1.10	-3.247	.003
20. Trouble in eating in front of family	1.37	0.85	2.03	1.13	-3.162	.004
21. Trouble in eating in front of others	1.50	1.04	2.23	1.22	-3.717	.001
22. Trouble in enjoying meals	1.37	0.81	2.10	1.06	-5.117	.000
23. Trouble in talking to other people	1.60	1.22	2.37	1.25	-4.173	.000
24. Trouble in taking on the telephone	1.43	0.90	2.07	1.20	-3.072	.005
25. Trouble in having social contacts with family	1.23	0.57	1.37	0.85	-0.891	.380

26.	Trouble in having social contacts with friends	1.10	0.40	1.83	1.05	-4.253	.000
27.	Trouble going out in public	1.50	0.97	2.03	1.07	-3.565	.001
28.	Trouble having physical contacts with family or friends	1.10	0.31	1.53	0.90	-2.765	.010
29.	Less interested in sex	0.97	0.61	0.97	0.61	0.000	1.000
30.	Less joy in sex	0.97	0.61	1.03	0.67	-1.439	.161
	Total	45.80	13.61	46.67	12.27	0.437	.665

IV. DISCUSSION

The present study investigated the quality of life of patients with maxillectomy after rehabilitation with obturator prostheses. In spite of numerous researches regarding the quality of life after cancer therapy, only a few studies emphasize on the quality of life of maxillectomy patients rehabilitated with obturator.14-15

In the present study, thirty patients were investigated. Depprich *et al.*10 studied forty three patients, Rogers *et al.*11 interviewed ten patients, Hertrampf *et al.*6 evaluated seventeen patients.

In the present study, a 35-item head and neck module (EORTC QLQ-H&N35) was utilized. This standardized questionnaire allows a comparison between multiple study groups.

The quality of life after rehabilitation with obturator prostheses was calculated to be 81.48% (± 13.64). The direct comparison of these results with the previous studies are not possible as in different studies, different tests and scales were used to evaluate the quality of life.

In most of the previous studies, similar to the study conducted by Depprich *et al.*,10 only the quality of life after prosthetic rehabilitation was evaluated by a cross-sectional study whereas in the present study, the quality of life before prosthetic rehabilitation as well as the quality of life after prosthetic rehabilitation have been assessed by a longitudinal study, thereby enabling us to simultaneously evaluate the change in the quality of life scores, which was found to be in order of significance of change as 0.665.

In the present study, age of patients ranged from 20 to 76 years. Majority of patients belonged to age group <30 years and age group 51-60 years respectively, showing a bimodal age distribution. There were only 2 patients in age group >70 years. Mean age of patients was 46.83 ± 16.98 years. For younger patients, the quality of life score was 73.02% in comparison to the score of older age group which was 87.78% after prosthetic rehabilitation. Elderly patients, who anticipate to have age related physical illness, suffer less from distress related to cancer as compared with younger patients who feel that their life span has been shortened and their quality of life impaired due to the ailment.

Patients suffering from maxillofacial tumors develop coping strategies and so they gain an increase of quality of life after prosthetic rehabilitation. Most of the patients do not criticize their decision after knowing the treatment outcome and consider that being alive out-weighs the demerits of obturator therapy.

Good obturator function has been found to be responsible for improved quality of life.4,6,16,17 However, in the present investigation, only the quality of life of maxillectomy patients after obturator was assessed but other domains related to the obturator function and the effect of family behavior, which also contribute to the quality of life were not studied in detail.

The present study found that except for change in scores for senses, general health and sex, for all the other dimensions a significant change was observed. Except for pain, for all the other dimensions where significant changes were observed, mean scores were found to be significantly increased after treatment. For pain a significant reduction in mean scores was found. For both pre- and-post-treatment evaluations, minimum scores were observed for the dimension sex whereas maximum scores were obtained for the item eating. No significant change in physical status was observed following treatment ($P>.05$). The reduction in pain scores as found in this study is contradictory to the previous studies done by Hertrampf *et al.* and Rogers *et al.*

In the present study, at item-level, statistically significant decrease in mean scores was observed for the items pain in mouth, soreness in mouth and coughing. A statistically significant increase in mean scores was observed for items - problems in swallowing solid food, problem in opening mouth wide, trouble in eating, difficulty in eating food in front of family and other people, problem in enjoying food, difficulty in conversation to people and on the telephone, problem in making social contacts with friends, trouble in making public appearance and difficulty in making physical contacts with others. The above observations of the present study are supported by the results obtained from study conducted by Depprich *et al.*10. In the present study, surgery alone (n = 19; 63.3%) was the most common treatment modality availed followed by surgery + radiotherapy + chemotherapy (n = 5; 16.7%), surgery + radiotherapy (n = 4; 13.3%) and surgery + chemotherapy (n = 2; 6.7%). According to the study conducted by Depprich *et al.*10, the most common treatment modality was surgery only.

It was found that squamous cell carcinoma was the most common clinical diagnosis (50%) followed by adenoid cystic carcinoma of hard palate (n = 4; 13.3%). Malignant melanoma (n = 3; 10%) and nasopharyngeal angiofibroma (n = 2; 6.7%) were the next most common diagnosis. Ameloblastoma, cleft lip and palate, cystic lesion, giant cell tumor, osteoclastoma and sinonasal solitary fibrous tumor were present in 1 (3.3%) case each.

The hypothesis that the quality of life of maxillectomy patients after obturation is acceptable is justified by the results of the present study. Future research on defect related newer obturator designs may help to overcome the problems typically associated with obturator prostheses and will help to improve patient's quality of life after maxillectomy in the future.

V. CONCLUSION

Obturator prosthesis is a highly positive and non-invasive approach to improve the quality of life of patients with maxillectomy defects.

Introduction

Implant dentistry has become an excellent treatment modality since its inception into the modern era of dentistry. It not only allows for a conservative and esthetic alternative to treating partial edentulism, but it also provides a stable foundation for treating complete edentulism. Dental implants can be a viable treatment option when there are sufficient quantity and quality of bone. However, when patients present with deficient alveolar ridges, it could jeopardize the application of implant dentistry. This problem is especially magnified in the posterior maxilla where ridge resorption and sinus pneumatization, compounded with a poor quality of bone, are often encountered. The procedure of choice to restore this anatomic deficiency is maxillary sinus floor elevation (sinus lift).⁽¹⁾

The maxilla itself is different in its function, physiology, and bone density than the mandible. These differences, in combination with the unique and varied anatomy of the

maxilla, pose a challenge to the surgeon in creating bone height and width sufficient for implant placement in harmony with planned prosthetic rehabilitation. However, a thorough knowledge of contemporary augmentation procedures mitigated by proper patient selection can lead to effective long-term solutions in the management of the deficient posterior maxilla⁽²⁾.

Implants can either be inserted simultaneously, when there is sufficient bone height for primary Stability (>4 mm), or can be inserted in a second procedure when bone-remodelling of the graft has taken place. This two-stage procedure is indicated when no good primary stability can be expected (bone height< 4 mm).⁽³⁾

Conditions such as sinus floor convolutions, sinus septum, and transient mucosa swelling and narrow sinus may form a (usually relative) contraindication for sinus floor elevation. Absolute contraindications are maxillary sinus diseases (tumours) and destructive former sinus surgery (like the Caldwell-Luc operation).⁽³⁾

Surgical techniques in sinus lift

Currently, there are mainly two approaches to the maxillary sinus floor elevation procedure, according to the literature. The first approach is lateral antrostomy, which is the classical technique and more commonly operated technique that was originally described by Tatum. More recently, Summers advocated a second approach known as the crestal approach, using an osteotome. This crestal approach is considered to be a more conservative method for sinus floor elevation.

Lateral Antrostomy: Lateral antrostomy is started with a crestal incision made on the alveolar ridge. Mostly, the incision is performed slightly palatal to the crest to preserve a wider band of keratinized attached gingiva for more solid wound closure and to avoid wound dehiscence. A Maxillary full-thickness flap is then raised to allow access to the lateral antral wall. Once the flap has been raised to the desired level, antrostomy is usually performed with a round bur to create a U-shaped trapdoor on the lateral buttress of the maxilla. Precaution must be taken so that the height of this trapdoor should not exceed the width of the sinus (it can be measured in a computerized tomogram) to allow for a final horizontal position of the new floor. The sinus membrane is then gently lifted from the bony floor by means of an antral curette. Marx and Garg suggested using a cottonoid soaked with a carpule of 2% lidocaine with 1:100,000 epinephrine and left in the space created for 5 minutes so as to limit bleeding and allow for better visualization for further dissection. It is important to free up the sinus membrane in all directions (Anteriorly, posteriorly, and medially) before attempting to intrude the trapdoor medially. Space is created after the sinus membrane has been elevated by the intruded trapdoor. This space is then grafted with different materials to provide the platform for implant placement; numerous research projects have been published to

evaluate the prognosis of implants under different grafting materials. Autogenous bone remains the gold standard in bone grafting. Iliac crest, chin, anterior ramus, and tuberosity have all been mentioned as common Autogenous donor sites in maxillary sinus lift. Hydroxyapatite mixed with Autogenous bone or used alone has also been shown to be viable alternatives. Care should be taken not to overfill the recipient site because it will cause membrane necrosis.

Fig. 1: Intruding the U-Shaped trapdoor. Corners of the trapdoor should be rounded.

Implants are placed either simultaneously with the graft (1-stage lateral antrostomy) or after a delayed period of up to 12 months to allow for graft maturation (2-stage lateral antrostomy). The initial bone thickness at the alveolar ridge seems to be a reliable indicator in deciding between these 2 methods. If the bone thickness is 4 mm or less, initial implant stability would be jeopardized. Therefore, a 2-stage lateral antrostomy should be carried out. The reverse holds true for a 1-stage procedure. A 1-stage procedure is less time-consuming for both the clinician and the patient. However, it is more technique-sensitive, and its success relies heavily on the amount of residual bone. **Crestal Approach:** One of the drawbacks of lateral antrostomy is that it requires the raising of a large flap for surgical access. Summers proposed a conservative crestal approach using osteotome for maxillary sinus floor

elevation in 1994. This technique begins with a crestal Incision. A full-thickness flap is raised to expose the alveolar ridge. An osteotome of the smallest size is then tapped into place by a mallet or drill into the bone. Preoperative bone height underneath the sinus is measured to determine the desired depth for osteotome extension. Osteotomes of increasing sizes are introduced sequentially to expand the alveolus. With each insertion of a larger osteotome, bone is compressed, pushed laterally and apically.

Techniques of maxillary sinus lift

The sinus lift surgical technique has developed over time, and several minor variations now exist like “Antral membrane balloon elevation” by Smiler, “Distraction osteogenesis” by Boyne etc.

Maxillary sinus augmentation techniques

Direct sinus lift or lateral window technique.	Indirect sinus lift

Summer’s osteotome technique: 1994

As osteotomy preparation progresses toward the posterior, the surgeon usually notices a softer bone texture. The ability to drill accurately in the posterior maxilla diminishes with the loss of tactile sensitivity in the soft bone when using rotary instruments. Also, inadvertent sinus penetration and over the preparation of soft bone is

common with drills. Other factors, such as torquing of the handpiece and reproducing a consistent angle of penetration, become more demanding as bone density decreases in the posterior maxilla. Because of the problems of drilling in the maxilla summers developed a means of osteotomy preparation in which the bone is not removed. The objective of this technique is to maintain, if possible, all of the existing maxillary bone by pushing the bone aside with minimal trauma while developing an accurately shaped osteotomy.

Figure 2: Lateral Antrostomy intruded with trap door grafting material.

At the osteotome sinus floor elevation, bone piles up in front of the penetrating osteotome, allowing the sinus floor to be displaced upwards.

The osteotome technique attempts to retain all of the bone that is present and to take advantage of the softer bone quality by relocating the bone to suit the needs of the surgery. In contrast to drilling, the osteotome technique improves maxillary anatomy by widening the ridge as the instruments are inserted. The osteotomes, developed by the author (Summers Osteotome Kit), are shaped so that the next larger osteotome tip fits into the opening created by the previous instrument. Bone buccal and palatal to the osteotomy is pushed laterally with successive penetrations of the larger osteotome. In a narrow ridge, expansion of the buccopalatal dimension of the site is an inherent beneficial characteristic of the osteotome technique. This

is called a ridge expansion osteotomy (REO), in contrast to a drilled site, in which the buccopalatal bone width is not changed.

Figure 3

Ridge expansion osteotomy can be attempted at any location wider than 3mm.

Buccal and lingual bone moves laterally as the osteotome are inserted.

Other potential benefits of the osteotome technique include

1. Alteration of the anterior or posterior sinus boundary during a routine osteotomy.
2. More upright (less flared) positioning of implants. The osteotome technique provides greater flexibility for the surgeon to match opposing landmarks because of the REO feature.
3. Development of future implants sites.
4. Addition of bone into the osteotomy as the site is developed⁽¹⁷⁾.

Crestal core elevation (CCE) first described by Summers in 1995, is a modification of the osteotome sinus floor elevation (OSFE) and the bone-added OSFE (BAOSFE) approaches, which are suitable for immediate implant insertion but require ≥ 6 mm of bone between the sinus floor and the crest of bone. CCE may be a simple alternative to LWT (lateral window technique) when the quantity of bone does not permit immediate implant placement. Performing CCE involves vertical crestal drilling using a wide trephine bur up to the sinus cortex followed by displacement of the bony plug inward and raising the sinus floor with a wide concave osteotome. The technique may be implemented in patients with residual

bone height measuring 3 to 6 mm. A further modification of the summer's technique was suggested by Fugazzotto and De Paoli who used it concomitantly with extractions of the upper molars. The placement of deproteinized bovine bone mineral covered with an absorbable membrane or non-absorbable expanded polytetrafluoroethylene membrane minimized the loss of alveolar bone height and width after tooth removal and permitted implant placement after 4 to 8 months. (4). The osteotome sinus floor elevation procedure without grafting material, and immediate placement of tapered implants, might be applied in situations for which previously only the lateral approach was considered. (5). The osteotome technique can be recommended when more than 6 mm of residual bone height is present, and an increase of about 3 to 4 mm is expected. (6). The study consisted of 26 patients treated with 39 Brånemark implants (Nobel Biocare) placed Using the simplified osteotome technique between September 1997 and November 2004 (87 months). Implant length ranged from 10 to 15 mm, while the loading time . Ranged from 5 to 74 months (mean: 35.2 months). The success rate was 97.4%, according to Albrektsson's criteria. These preliminary data indicate that the simplified osteotome technique is an effective and safe technique. (7). Performing sinus elevations with osteotomes is a predictable technique that enables achieving an increase in bone height and successful results, similar to those of other techniques used in the placement of implants. (8).

The piezoelectric bony window osteotomy and sinus membrane elevation (Pbwo and Psme): 2001.

The most commonly used procedures, such as lateral bony window osteotomy technique and osteotome sinus elevation, have a problem of perforating the sinus membrane either with the burs during the osteotomy or with the manual elevators during the separation of the

membrane. If the bone graft is carried out in the case of a membrane lesion, it is very likely that parts of the bone graft will go to an ectopic site, usually on the surface of the respiratory mucous epithelium; this would entail the necrosis of the graft, followed by a suppurative process in the sinus cavity, generally visible in the Orosinus antral fistula. In 2001 Vercellotti et al. introduced a new technique for simplification of the sinus augmentation procedure, the piezoelectric bony window osteotomy and sinus membrane elevation (PBWO and PSME). This new technique uses a specifically engineered device, the Mectron Piezosurgery system, to perform the osteotomy.

Surgical procedure

With the blade of the 15 scalpels, a horizontal crestal incision is made at the top of the ridge from the distal aspect of the maxilla, continuing mesially until it reaches one or two of the anterior teeth, where a vertical releasing incision is made. Another releasing incision is made in the distal aspect under the Stenson's duct. A flap of the total vestibular thickness is raised. It is characterized by a broad vascular supply mesially and distally. The most apical parts of the two incisions are united by a horizontal periosteal incision to give greater elasticity to the mucous flap in the suturing phase.

Piezoelectric bony window osteotomy

To open the sinus window, the following surgical procedure is carried out. With the No. 1 scalpel from the Sinus Lift system by Mectron Piezosurgery, an outline is drawn. It begins with the most coronal horizontal incision, with a length of approximately 14 mm positioned approximately 3 mm apical to the residual crestal bone. Two vertical incisions of 6 to 7 mm are made and united at the top by another horizontal incision. The bony window is performed in the area of the second premolar–first molar. The outline is drawn in about 3 minutes, and the average thickness of the cut is approximately 1 mm. This

produces a bony window in which the frame is represented by the Schneiderian membrane (sometimes red in colour, sometimes blue). At this point, the osteotomy is completed by rounding the angles of the window.

PBWO made by No. 1 Piezoelectric scalpel. It is possible to observe the Schneiderian membrane, which appears as the frame of the bony window.

Different clinical case. The initial phase of PSME uses the overturned cone compressor.

Compressor is inserted into the frame of the window, separating the borders approximately 2 mm

Piezoelectric sinus membrane elevation

The No. 2 insert, a compressor in the shape of an overturned cone, is inserted into the edge of the frame of the membrane exposed by the osteotomy. It separates the borders approximately 2 mm with ease. At this point, the No. 3 insert (an angled periosteal elevator with rounded edges) or the No. 4 (a straight periosteal elevator), depending on the anatomic situation, is used in the following order. The first stage of the membrane elevation begins in the apical position.

PSME phase two: the elevator in position, ready to work.

First stage of the membrane elevation begins in the apical position, then in the mesial and distal aspects.

Once the membrane is elevated on three sides, it is possible to separate it from the floor of the sinus, where adhesions are very common, Therefore avoiding the risk of perforation.

The membrane separation in the apical direction depends on the length of the implants that will be placed in the second surgery. The insert is directed toward the mesial surface, separating the membrane until it meets the anterior walls of the sinus. The insert is then directed toward the distal walls, separating the membrane to obtain the volume required for the graft to build the future implant site. Finally, the insert is directed toward the crestal position, where it is possible to meet adhesions, particularly in the depths of the molar depressions. This maneuver is carried out last in a way that allows the separation of the membrane floor without tension, having already separated the membrane from the other sides of the window.

The sinus augmentation procedure is performed using an Autogenous bone graft mixed with Autogenous platelet-rich plasma gel. After the bone graft is performed, and the bioabsorbable membrane is positioned to cover the bony window and fixed to the bone with screws, horizontal mattress sutures are placed.⁽⁹⁾

A simple inexpensive method for precisely locating the floor of the maxillary sinus, as well as the presence of any septa, at the time of sinus augmentation surgery. Using an anaesthesia light wand placed transnasally to illuminate the sinus, the surgeon can reliably elevate the lateral maxillary wall overlying the sinus with relative ease without fear of placing the osteotomy cuts too far from the sinus floor. The same procedure can be used postoperatively to evaluate the density of the bone graft placed into the sinus prior to closure. (10)

Subantrosopic Laterobasal Sinus Floor Augmentation (Salsa) Technique: 2002

Engelke and Deckwer described a new endoscopically controlled technique for sinus floor augmentation. This technique involves trans alveolar mobilization of the sinus membrane controlled by sinuscopy, trans alveolar augmentation, and simultaneous implant placement and has been indicated for moderately reduced alveolar sites. Engelke and coworkers reported on a modified endoscopic technique, the laterodorsal tunnel technique, which allowed augmentation of multiple maxillary sites via 1 small laterobasal trepanation (unpublished data). Through this approach, a “tenting” of the complete sinus membrane from the premolar to the second molar site could be performed, thus allowing for large

GUNTUR-522509, A.P., India.

augmentations in case of primary and secondary implantation. Both procedures are controlled with the endoscope placed in the lumen of the maxillary sinus via a puncture of the canine fossa.

Surgical procedure

The flap design depends on the number and location of implants planned. Typically, a crestal incision is made with a vestibular relief incision in the first premolar region. A full-thickness mucoperiosteal flap is then elevated, exposing the anterobasal aspect of the sinus wall, including the inferior third of the zygomatic buttress and the alveolar crest with the planned implant sites.

Microsurgical Access: A 5-mm-diameter laterobasal osteotomy is made directly anterior to the zygomatic buttress at the inferior aspect of the anterior sinus wall. The osteotomy is performed with a 4-mm diamond round bur under magnification with the support video endoscope technique. The osseous margin of the trepanation is then identified. The sinus membrane is displaced with the help of microsurgical elevators of 2 to 4 mm in diameter around the trepanation. The bony access is opened just enough to allow the introduction of 4-mm-diameter angulated mucosal elevators into the subantral space. The circular dissection of the sinus membrane is performed under continuous micro – endoscopic observation on a monitor.

Microsurgical elevators: type T for tunnel preparation

After circular detachment, the access hole is rounded and extended to a diameter of 5 mm. Its position is always located at the most inferior aspect of the alveolar recess to facilitate the laterobasal tunnelling.

Creation of the SAS: The SAS is created by tunnelling the sinus membrane with elevators of 0-, 45-, and 90-degree angulation under tactile control with the osseous basal floor. Primarily the membrane at the laterobasal angle of the sinus floor is detached in an anteroposterior direction. The detachment ended 5 mm dorsal to the projected most distal implant site. If necessary, the complete sinus floor is tunnelled this way. The tunnel then is extended at its medial and superior aspects.

The instruments have to be guided continuously in close contact with the bone to avoid tension or perforation of the sinus membrane, particularly if irregularities of the sinus floor or difficult anatomy are present. In case of septa or irregular shape of the sinus floor, endoscopic exploration helps to lead the elevators along the basal limits of the bony maxillary wall. The tunnel size depends on the height and volume planned for the augmentation and implants. Enough space has to be provided to place the graft material without tension on the sinus membrane.

Endoscopic Control of the SAS

After detachment of the sinus membrane, the subantral space is examined via the access trepanation using the

70-degree and 30-degree endoscopes. The examination includes circular identification of the boundaries of the SAS and inspection of the entire sinus membrane forming the roof of the SAS for perforations or tears.

Microsurgical access to the subantral space.

Subantrosopic examination of the subantral space.

(Left) Normal appearance of the sinus membrane representing the roof of the artificial subantral space. (Right) Twist drill (Oraltronic, Bremen, Germany) entering the subantral space.

Sinus membrane examination. During respiration, alternating movement of the sinus membrane is

observed, giving evidence of the absence of perforations

Stepwise augmentation. Augmentation material is placed first at the distal and proximal ends of the subantral space and is controlled endoscopically before the periapical Spaces around the implants are filled.

If a perforation of the sinus membrane is detected, immediate repair is performed using polyglactine mesh (Vicryl, Ethicon). Finally, the length, height, and width of the subantral space are measured.

Preparation of Implant Cavities: Primary implant cavity preparation is carried out if primary Stability of the implants could be achieved. Within the subantral space, the sinus membrane is protected with elevators, while the basal bone is perforated with the implant burs. The implant cavity has to be surrounded by at least 5 mm of SAS to allow the membrane to tent up adequately during augmentation.

Endoscopically Controlled Stepwise Augmentation: The first portion of the augmentation is placed at the most distal part of the SAS. The desired “tenting up” of the membrane is checked endoscopically before covering the mesial aspect of the most distal implant with augmentation material. Proceeding from the distal extreme toward the entrance access hole, the inter implant spaces and periapical spaces around the implants are subsequently covered, with intermittent endoscopic control. Before the implant is placed adjacent to the access trepanation, the most mesial (anterior) aspect of the SAS is filled with

augmentation material. The entrance keyhole is then covered with a mucoperiosteal flap.

Primary or Secondary Implant Placement: Implants are placed primarily, if primary Stability could be achieved. In the absence of primary Stability or if the bone structure is obviously insufficient, secondary placement is carried out after at least 6 months of healing time. (11). From October 1999 to December 2000, of 92 sinus floor elevations, 18 were carried out endoscopically controlled with an osteotome technique. As augmentation material, -tricalcium phosphate (-TCP) or autogenous bone was used; 22 implants were placed. With the ECOSFE, (Endoscopically controlled osteotome sinus floor elevation) perforations of the sinus membrane can be visualized; however, they cannot be avoided. Although this technique is less invasive than the lateral window technique, it cannot be recommended as a standard procedure in the posterior maxilla because of the large amount of additional equipment needed and the technically demanding procedure. (12). Sinus floor augmentation has become a routine procedure with predictable results. Flapless implant placement is recommended for a series of indications with sufficient bone volume. Flapless surgery in the atrophic maxilla is presented as a refinement of the endoscopic Subantrosopic laterobasal sinus floor augmentation (SALSA) technique. Subantral space is augmented using the SALSA technique without raising a mucoperiosteal flap. Implants are placed transgingivally without raising a mucoperiosteal flap, with endoscopic control of the cover screw at the bone level. In a case series of 6 patients, 21 implants were placed and augmented simultaneously. The mean augmentation height was 10.7 mm (range, 5.7 to 16.6 mm); the mean residual bone height was 5.1 mm (range, 1.9 to 12.1 mm). Complications such as insufficient primary Stability and sinus membrane

perforation were treated without changing to an open surgical approach. (13).

Boyne's distraction osteogenesis technique

2004 Distraction osteogenesis is a biomechanical process of bone tissue formation, where the distraction forces which act between the bone segments affect the biological potential of the bone by forming a callus of determined length and height. Distraction osteogenesis is preceded by Corticotomy or sub-periosteal osteotomy and followed by fixation of the distractor on the segments and their gradual lengthening. Codvilla, in 1905 was the first to perform extremity lengthening by the application of external traction. The credit for popularizing the technique worldwide goes to Gavril Ilizarov, a Russian orthopaedic surgeon. In the late 1980s he published in America for the first time his research and clinical results on the bone distraction, causing a wave of developments in the bone distraction technique worldwide. Snyder et al., 1973 were the first to apply the Ilizarov principles of distraction osteogenesis is for the regeneration of the osteotomized mandible. (17).

A diagrammatic representation of a Papio anubis dry specimen skull outlining the area of the osteotomy (O) for the DO in the maxillary canine, molar, and

premolar region. (The outline of the maxillary sinus is shown) (S). (C) indicates areas of vertical cuts made to obtain biopsies for control maxillary alveolar bone to compare with the DO regenerated area. (Bottom) A higher power view of the surgical site is shown.

In 2004 Boyne PJ et al have applied this distraction osteogenesis technique to increase height of the maxillary sinus floor. In this animal study the posterior maxilla's of 3 adult Papio Anubis baboons are rendered edentulous from the lateral incisors anteriorly, to the third molars posteriorly; and alveolectomies are performed to simulate post-extraction alveolar ridge atrophy. After 12 weeks of uneventful healing, osteotomies are performed bilaterally in the edentulous areas with the horizontal section extending from the lateral incisor area to within 5 mm of the mesial surface of the retained and fully erupted third molar tooth. The superior extent of the osteotomy section is located at the level of the sinus and nasal floors in the midposterior portion of the bony section. The location of the horizontal osteotomy for the DO is calibrated by making a small 3 mm osteotomy opening in the lateral wall of the nose and sinus. A periodontal probe is inserted between the nasal-antral membrane and the bony wall of the nasal sinus and extended down to the osseous floor. By this method of measurement, it is possible to determine how much bone remained between the sinus floor and the alveolar crest so that the osteotomy cut could be made according to the design of the study. The osteotomy cut is made to leave anteriorly and posteriorly approximately 1 to 1.5 mm of alveolar bone height to accept the screws for the distractor plate. The midposterior portion of the osteotomy is fashioned to actually interdict the floor of the antrum for a distance of approximately 8 to 10 mm in antral floor.

Intraoperative view of the Surgical site

A view of a small osteotomy (SO) made in the lateral wall of the maxilla and the insertion of a measuring probe by which it is possible to determine the height of the nasal and antral osseous floor remaining in the maxilla. By this method, it is possible to direct the periapical maxillary osteotomy section (arrow) to interdict the floor of the antrum in the mid posterior portion of the osteotomy cut. The nasal and antral mucosa was elevated from the inferior portion of the sinuses by a small curette placed through this osteotomy opening. Note the thin Alveolar ridge crest (ARC).

Fixation of the base plate portion of the DO device is obtained by placing the screws superior to the sinus floor into the lateral antral-nasal wall. The transport segment of the device containing the residual crest of the alveolar ridge is only 1 to 1.5 mm in height, which is minimally sufficient to accept the screws of the transport portion of

the DO device. After a latency period of 7 days, the distractor (12 mm; KLS Martin, Jacksonville, FL) is activated at the rate of 1mm per day for 10 days. The postoperative course is uneventful⁽¹⁸⁾.

A view of the positioning of the distractor which is being guided by the marking probe in the sinus wall. The screws securing the inferior transport segment are engaging the thin alveolar crest which measures only 1 to 2 mm in height below the osteotomy. The thinness of the alveolar crest (transport segment) (ARC) and the attachment of the base plate at the lateral maxillary wall are visualized.

Complications

Complications may be encountered during and after maxillary sinus elevation procedures. Surgical procedures involving bone grafting and implants in the maxillary sinus have potential complications that can be specific or non-specific for these procedures. For the sinus graft, perforations of the Schneiderian membrane are the main intraoperative complication, which occurs in 7% to 35% of the procedures. Postoperative complications are less common and consist mostly of acute or chronic sinus infection, bleeding, wound dehiscence, exposure of barrier membrane and graft loss. Intraoperative complications may lead to post-operative complications. Surgical complications did not significantly influence implant survival. When performing sinus augmentation, bone substitute materials are just as effective as autologous bone, whether used alone or in combination with autologous bone. Implant surface treatments can have an important

effect on implant survival, and it would appear that roughened surfaces are the best option. When implants are inserted simultaneously to grafting, a higher failure rate can be expected. In 100% of cases, the AAA (Alveolar antral artery) was found to be partially intra-osseous, that is, between the Schneiderian membrane and the lateral bony wall of the sinus, in the area selected for sinus antrotomy. Hence a sound knowledge of the maxillary sinus vascular anatomy and its careful analysis by CT scan is essential to prevent complications during surgical interventions involving this region.

Conclusion

An inadequate bone quantity and quality have been considered for many years as absolute contraindications for implant-supported rehabilitation. The risk of implant failure in the posterior maxilla is generally high because of the low bone density and the progressive ridge resorption caused by edentulism. Implant treatment in the atrophic posterior maxilla must be carefully planned and may require a pre-prosthetic surgical intervention of bone grafting. Maxillary sinus floor augmentation is often performed to create conditions adequate for implant placement. The implant success rate and the predictability of the maxillary sinus augmentation procedure depend on numerous factors. However, because of the improvement of surgical techniques and the progress of research in the field of biomaterials, excellent outcomes have been reported in the last years. Recent systematic reviews of the literature have demonstrated that sinus floor augmentation procedure is well documented with an overall implant survival rate well beyond 90%.

Effect of autoclaving on the cyclic fatigue resistance of nickel-titanium rotary instruments: An *in vitro* study

Kukunuru Gayatri, Sravanthi Tammineedi, Nagesh Bolla, Sayesh Vemuri, Ram Chowdary Basam, Chukka. Ram Sunil

Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Aim: The aim of the study is to determine the effect of autoclaving on the cyclic fatigue resistance (CFR) in respect to three different rotary nickel-titanium (NiTi) systems.

Methods: Three rotary NiTi files with different manufacturing process were selected and arranged into three groups. Group 1: Neolix Neoniti files ($n = 15$), Group 2: Edge Files ($n = 15$), Group 3: NeoendoFlex files ($n = 15$). Each group was then subdivided into three subgroups containing 5 samples each based on the number of cycles of autoclaving (0, 1, 5 cycles). The instruments were subjected to autoclave without usage. The files of size 25, taper 6%, and 25 mm length were taken. After the autoclaving cycles, the files were rotated in cyclic fatigue testing device with simulated canal curvature of 60° until file separation. Time taken for the instrument separation (in minutes) was multiplied by the number of rotations per minute to attain the mean number of cycles to failure for every file. The obtained results were subjected to statistical analysis using two-way ANOVA and Newman-Keuls multiple *post hoc* procedures.

Results: Neolix Neoniti files exhibited the maximum CFR (98.80) than EdgeFiles (80.47) and Neoendo Flex files (41.80) ($P = 0.0001$). Reduction in CFR was observed with increase in the number of cycles of autoclaving (i.e., 0, 1, 5 cycles).

Conclusion: Autoclaving has a negative influence on the CFR of the rotary NiTi files used. Neolix Neoniti files exhibited greater CFR than EdgeFiles and Neoendo Flex files.

Keywords: Autoclaving; cyclic fatigue; EdgeFiles; Endodontic rotary file; Neoendo Flex files; Neolix Neoniti files; nickel-titanium

INTRODUCTION

In 1988, Walia suggested the use of nickel-titanium (NiTi) alloy named as nitinol in the manufacturing of rotary instruments owing to its superior mechanical properties such as shape memory and superelasticity.^[1,2] These properties of NiTi alloys are responsible for the austenitic to the martensitic phase transformation. Either the process

of cooling or the application of stress causes phase transformation in the NiTi alloy and is thermoelastic in nature. The mechanical properties and the transformation temperatures of Ni-Ti alloys are strongly dependent on their chemical composition and thermomechanical processing. A thorough knowledge of the physical properties and limitations of endodontic files can reduce undesirable procedural errors, like file separation in the canal, transportation, and strip perforation.^[3]

Cyclic fatigue is due to numerous cycles of tension and compression that eventuate when a file rotates in the

curved canals. The rotary files tend to fracture at a certain point when it reaches its flexural limit.^[3] Most rotary NiTi endodontic instruments are produced by grinding. Some of the rotary NiTi files are produced by twisting the alloy after it had been subjected to heat treatment. Literature had revealed many studies regarding the effects of operating rate, instrument design, surface treatments, root canal irrigants upon the cyclic fatigue resistance (CFR) of rotary NiTi files. Possible strategies to improve the CFR comprises either improving the process of manufacturing or utilize novel alloys having excellent properties. Thermal processing methods optimize the microstructure of the NiTi alloy, thus affecting the CFR of the instruments.^[4-7]

Accurate determination of CFR requires utilization of natural root canals. However, after usage the root canal anatomy will change and the samples cannot be reused. Thus, it becomes difficult to standardize the experimental setting. Consequently, several equipments such as glass and metal tubes were used for determining CFR. Nonetheless, there is no international laboratory standard for determining the CFR of rotary NiTi files.^[8,9]

According to the manufacturers, rotary NiTi files are single use. However, in clinical settings, these are frequently reused after sterilization. After multiple uses, surface defects such as pitting, strip formation, microfractures/microcrack formation, and disruption of cutting edges are apparent on the instrument surface. Upon further use, the instrument may fracture.^[10]

Zinelis *et al.* stated that heat treatment of the apical 5-mm portion of a NiTi rotary instrument can extend its fatigue life by reducing its residual strain. Furthermore, NiTi files have more CFR when subjected to heat treatment at 430°C which results in superior elastic behavior and provides better shaping ability. When the instrument is heat treated at 600°C, the NiTi alloy undergoes martensitic and R-phase transformation. At this temperature, due to the recrystallization of NiTi alloy, decrease in the surface hardness will be evident. Hence, the heating temperature is an essential aspect closely related to the performance of NiTi alloy.^[11]

Literature search showed that autoclaving has effect on the behavior of rotary NiTi files with varying conclusions. Some researchers concluded that autoclaving negatively influences the physical properties of rotary NiTi files and causes files to fail prematurely. Other researchers have reported that autoclaving for 10 times did not impact the fracture predilection of rotary NiTi files.^[3,12] The unique properties of NiTi alloy such as superelasticity and shape memory are greatly influenced by the manufacturing procedure of the file.^[8,11] Yahata *et al.* had stated that the flexibility of the rotary NiTi instruments might improve when they are subjected to heat retreatment during

autoclaving.^[13] Sundaram *et al.* have suggested that sterilization temperatures above 125°C could reverse the NiTi deformation caused during clinical use.^[10]

Three different NiTi file systems were selected based on the criteria that they were produced by different manufacturing process and of different cross-sections. Neolix Neoniti files have nonhomogenous rectangular cross-section and are manufactured using wire-cut electric discharge machining (WEDM) process.^[14] The EdgeFile system has parabolic cross section and is manufactured using proprietary annealed heat treatment forming a branded fire wire.^[15] Neoendo Flex files have triangular cross section and are subjected to gold thermal treatment.^[16]

The main objective of the present research is to estimate whether autoclaving process has any influence on the CFR of newly introduced heat-treated rotary files, i.e., Neolix Neoniti, EdgeFiles, and Neoendo Flex file systems.

METHODS

Sample size calculation

The sample size was estimated using the G*power, version 3.1.9.4 (Franz Fauluniversitat, Kiel, Germany). Sample size was estimated with α -error is 5% and power of the test is 80% or 20% β -error with effect size of 0.6. Hence, it was calculated as 15 subjects in each group.

Three groups of rotary NiTi instruments of identical tip size of 0.25 mm and 6% taper were taken: Group 1-NeolixNeoniti files (Chatres-la-Forêt, France), Group 2-EdgeFile X3 (EdgeFile, Albuquerque, New Mexico, USA), Group 3-Neoendo Flex files (Orikam, India). Each file group consists of 15 instruments. It was further divided into three subgroups containing five instruments, each based on the number of autoclaving cycles, i.e., Subgroup A-no autoclaving, Subgroup B-one cycle of autoclaving, and Subgroup C-five autoclaving cycles. Autoclaving process was carried out at a temperature of 121°C for 15 min duration, 15lb pressure, which is followed by 15 min of drying. Finally, all the files were tested for CFR. A customized equipment was used for determining CFR. This equipment incorporates a stainless steel block with simulated canals [Figure 1]. The mounted handpiece enables correct positioning of every file into the simulated canal. Each file was tested in the customized artificial canal having 60° curvature angle and 5 mm of curvature radius. Each file was used at a rate of 300 rpm in a 16:1 contraangle reduction handpiece activated by a torque modulated endodontic motor (X Smart Endomotor, Dentsply Maillefer, Switzerland) till file separation had taken place. The time taken for the file separation was noted utilizing the stopwatch and video camera.

Number of cycles to failure (NCF) = Time taken for file separation (In minutes) × Number of rotations per minute.

Statistical analysis

Mean values of NCF and its standard deviations were evaluated for the samples. Two-way ANOVA test was used to calculate significant differences among the groups. Once the analysis revealed a significant difference, Neuman–Keuls *post hoc* test was done to calculate the mean differences (with $P < 0.05$). The data analysis was carried out utilizing SPSS 20.0 version software (IBM, Bangalore, Karnataka, India).

RESULTS

Higher NCF is observed in Group 1 (98.80) when compared to others. Least NCF is observed in Group 3 (41.80) (Graph 1). Mean NCF in Group 2 is 80.47. Two-way ANOVA comparison [Table 1] showed that the mean NCF is dissimilar in different groups which is statistically significant ($P = 0.0001$). The mean NCF of three subgroups (A, B, C) was also dissimilar which is statistically significant ($P = 0.0002$). However, there is no statistically significant difference in the interaction effect of three main groups (1, 2, 3) and three subgroups (A, B, C) with respect to NCF.

Pairwise comparisons of groups [Table 2] revealed a significant difference between Groups 1 and 2 ($P = 0.0211$),

Figure 1: Cyclic fatigue testing machine with mounted handpiece

Groups 1 and 3 ($P = 0.0001$), Groups 2 and 3 ($P = 0.0001$). The mean NCF is in the order of Group 1 >2>3. Pairwise comparison of subgroups revealed a significant difference only between Subgroup A and C ($P = 0.0262$). A nonsignificant difference was observed between Subgroups A and B ($P = 0.1105$) and Subgroups B and C ($P = 0.2895$).

DISCUSSION

The main purpose of autoclaving rotary files is to eliminate the microbial contamination, thereby increasing the chance for the success of root canal therapy.^[12] Several clinicians choose having fixed sets of particular files. However, all these files might not be used during the treatment. Therefore, the rotary files that have not been utilized are also exposed to multiple cycles of autoclaving. Majority of the studies in the literature had analyzed the influence of frequent autoclaving on the rotary NiTi file systems.^[2,17,18]

Autoclaving has a negligible influence on the physical properties of stainless steel instruments. Silvaggio and Hicks concluded that autoclaving of rotary NiTi files did not raise the probability of file fracture.^[10,19] Dissimilarities in the CFR among rotary NiTi files are owing to the differences in many factors such as the process of manufacturing, operational features, file design, characteristics, canal curvature, and the method of fatigue failure testing. Methods to improve the longevity of the NiTi instruments include the following: (i) thermal treatments before machining; (ii) appropriate machining conditions of the NiTi alloy; and (iii) electro-polishing.^[11]

According to Aminsobhani M *et al.*, the Austenite start temperatures of Neolix Neoniti file were in a manner that at the mouth temperature, the austenite phase existed. Neoniti reveals R-phase transformation.^[20] The austenite-finish temperatures of Neoniti were higher than human body temperature, therefore, material was in the phase transformation from martensite to austenite, gives the instruments more flexibility when used in the clinical situation.^[21] The EdgeFile files and Neoendo files are predominantly in austenite phase at room temperature.

In the present study, Neolix Neoniti files showed the highest CFR than EdgeFiles and Neoendo Flex files. It could be due

*Significant. SD: Standard deviation

to differences in the manufacturing process of the three file groups. Neolix Neoniti files have a nonhomogenous rectangular cross-section, and it has multiple tapers in a single instrument. It is manufactured using the WEDM process. This manufacturing process improves the flexibility and shape memory of this system.

These observations are in compliance with previous studies.^[14,22] Neolix Neoniti files showed highest CFR than RaCe, Mtwo, Twisted file, and ProTaper Next X2 files.^[22] This may be due to the unique manufacturing process and heat treatment of this file. WEDM process creates an electrical discharge which produces sharp cutting ends, changing variable profiles, and flexibility in the rotary NiTi file systems.

Rubio *et al.* compared the cyclic fatigue resistance of 10 different types of endodontic files and concluded that the instruments manufactured with CM wire technology, i.e., Hyflex EDM and Neoniti were superior to other endodontic files, and there was no statistically significant difference between Hyflex EDM and Neolix files.^[23]

EdgeFiles have better CFR when compared to Neoendo Flex files. This can also be imparted to the manufacturing difference between the two file systems. The EdgeFile system has a parabolic cross-section. This system undergoes proprietary annealed heat treatment, forming a branded firewire that increases NiTi instruments' flexural strength and flexibility.

Adigüzel *et al.* evaluated the CFR of EdgeFile X3 files with One Curve, One Shape, and 2Shape files *in vitro*. They concluded that EdgeFile system showed highest CFR than the other groups tested. EdgeFile system was manufactured using Firewire technology that is responsible for its improved CFR over the other file systems.^[24]

According to Tanomaru-Filho *et al.*, the heat treatment CM that is applied to the ProDesign and HyFlex CM systems contributed positively to the best results presented in relation to instruments without heat treatment (MTwo) or with FireWire heat treatment (EdgeFile).^[15] Neoendo Flex files exhibited minimum CFR in the present study. The

current results are in accordance with the research done by Mahajan *et al.*^[16] They stated that Neoendo Flex files exhibited less CFR than One curve files. Other reason for better CFR of Neolix Neoniti files could be attributed to its rectangular cross section which contributes to bulk of the instrument when compared to parabolic cross section of edge file and triangular cross section of Neoendo files.^[14]

It is also observed that, after every autoclaving cycle, there was a marked reduction in CFR of rotary NiTi files. Hilfer *et al.* inferred that frequent autoclaving markedly reduced the NCF of size 25, taper 6% Twisted Files.^[12] Nair *et al.* conducted an atomic force microscopy and proposed that the roughness on the file surface became more pronounced with numerous autoclave cycles.^[25] Limitation of the present study is that the endodontic files were rotated in a stainless steel simulated canal. However, the files may behave differently when instrumented in a natural tooth. Hence, the results may slightly vary in the *in vivo* settings. Lubricating agent was not used in the present study. Hence, the effect of the presence of lubricating agents on the CFR of these files also needs to be evaluated.

CONCLUSION

This study concluded that Neolix Neoniti files, which were manufactured using EDM technology, exhibited highest CFR compared to EdgeFiles and Neoendo Flex files. Reduction of CFR in the rotary NiTi files was observed with an increase in number of cycles of autoclaving.

Management of Bilateral Maxillary Second Molars with Extra Palatal Root: A Case Report

SHAIK RESHMA PARVEEN¹, BANDLAPALLY SREENIVASA GUPTHA ANILA²,
SRAVANTHI TAMMINEDI³, SAYESH VEMURI⁴, NAGESH BOLLA⁵

ABSTRACT

A crucial understanding of teeth' internal and external anatomy is critical for the successful outcome of endodontic therapy. The presence of two palatal roots in maxillary molars, particularly in the second molar, is rare. The present case report addresses this anatomical variation in an 18-year-old female patient with a chief complaint of severe pain in the upper left back teeth region since one week. Preoperative radiographic evaluation of maxillary second molar did not reveal the aberrant anatomy due to its location and impaction of maxillary third molar onto the roots of the second molar. After access opening, inspection of the pulp chamber floor revealed a slightly deviated location of the palatal canal and a bleeding point mesial to the palatal canal. Intensive exploration for determining any additional canals was done using David Green (DG) 16 endodontic explorer under 3× magnification using dental loupes. A narrow field of view Cone Beam Computed Tomography (CBCT) was obtained to evaluate the unusual root canal morphology. Following a thorough analysis of CBCT, root canal treatment was performed employing a standard protocol. This case report highlights the successful diagnosis and management of the bilateral maxillary second molar with two separate palatal roots. With CBCT and magnification, determining the root morphology and canal configuration will be more accurate, further improving the quality of root canal treatment.

CASE REPORT

An 18-year-old female patient with a non contributory medical history presented to the Department of Conservative Dentistry and Endodontics with the chief complaint of pain in her maxillary left back tooth region for one week. The pain was intermittent throughout the day, non radiating, aggravated by taking cold, hot foods and on mastication. The patient gave a history of previously initiated root canal therapy from a private dental center one week back. Due to the Coronavirus Disease (COVID) pandemic, the previous clinician was unavailable and hence she visited our institute. Clinical examination revealed a tooth restored with temporary filling with respect to 27, tender on percussion with no associated swelling. Pulp vitality testing of the involved tooth showed no response to electronic pulp tester (SybronEndo, Orange, CA) and cold (Endofrost, coltene). Preoperative radiographic evaluation revealed an access cavity filled with radioopaque restorative material with a slight widening of periodontal ligament space with respect to 27.

Hence, a diagnosis of previously initiated root canal therapy with symptomatic apical periodontitis was established based on clinical and radiographic findings [Table/Fig-1]. Informed consent was taken and the tooth was anaesthetised with posterior superior alveolar nerve block using 2% lignocaine (Astra Zeneca Pharma India Limited, Bangalore, India) and isolated with a rubber dam (Coltène/ Whaledent, OH, USA). After temporary restoration removal, pulp chamber revealed three canals and a bleeding spot in the floor of the pulp chamber mesial to the palatal canal and was assumed as perforation. The Intraoral Periapical (IOPA) radiograph of the concerned tooth did not offer any conclusive information. Inspection of the chamber floor for determining any additional canals was done using DG 16 endodontic explorer (Hu-Friedy, USA) under 3X magnification using dental loupes (Daray, Derbyshire). Intensive exploration revealed a catch at the bleeding point. A sterile cotton pellet was placed inside the pulp chamber, and the access cavity was sealed with Intermediate Restorative Material (IRM) (Caulk, Dentsply, USA).

A CBCT (Carestream/Trophy, Marne-la-Vallée, France) of the partial arch was taken with exposure parameters of 120 kV and 5.0 Ma to evaluate whether it is an extra canal or an extra root and also to study its anatomy. An ultra-low radiation dose scan was done using a focused field of view. The images were reconstructed at 0.2 mm thickness increments. Axial view of CBCT with respect to 27 showed the presence of an additional palatal root [Table/Fig-2a-c].

[Table/Fig-1]: Preoperative radiograph in which access opening has been done #27 with arrow mark depicting widening of periodontal ligament space at the periapex.

[Table/Fig-2]: a,b&c) Transverse section of CBCT showing four roots with four canals at a) cervical, b) middle, c) apical third respectively # 27 (MB mesiobuccal DB distobuccal MP mesio-palatal DP disto-palatal respectively).

Tooth 27 had four canals with four roots mesiobuccal, distobuccal, mesio-palatal, distopalatal. Initial instrumentation was performed using a 10 k-file (Mani, Inc, Tochigi, Japan). Coronal enlargement was done with Hyflex Electrical Discharge Machining (EDM) orifice opener (Coltene- Whaledent, Allstetten, Switzerland) to obtain straight-line access. Each canal's working length was determined using an electronic apex locator (Root ZX, J Morita Mfg. Corp., Japan) and confirmed radiographically with an IOPA [Table/Fig-3a]. Glide path was established with 10/ 05 Hyflex EDM file ((Coltene-Whaledent, Allstetten, Switzerland) followed by which canals instrumented with Hyflex EDM rotary files till 25/~ (Coltene-Whaledent, Allstetten, Switzerland). Copious irrigation of the canals was done with 5ml of 3% NaOCl (Sodium Hypochlorite) (Vensons India, Bengaluru, India) and 5ml of 17% Ethylene Diamine Tetra-acetic Acid (EDTA) (Prime dental Pvt., Ltd., Thane) liquid between each file. With each irrigation flush of NaOCl and EDTA, sonic agitation of irrigant was done using an endoactivator (Dentsply Sirona) for one minute. Distilled water (Milli-Q water system, Millipore Corporation, Bedford, MA, USA) was used as the final irrigant. Root canals were dried with paper points and obturated with corresponding 25 size gutta-percha (Coltene-Whaledent, Allstetten, Switzerland) and AH plus sealer in the same visit (Dentsply, Konstanz, Germany) [Table/Fig-3b]. Finally, the tooth was restored with a bulk-fill composite restoration (EverX Posterior (EP)/GC Europe [Table/Fig-3c]. At one month follow-up, due to financial constraints and less interocclusal clearance, cast metal crowns were delivered for the patient. After one year, the clinical and radiographic follow-up revealed that the patient was asymptomatic and periapical tissues were healthy [Table/Fig-4].

[Table/Fig-3]: a-c) Radiograph showing working length of all four roots #27, Master cone placement #27, Postoperative radiograph of maxillary second molar restored with bulk fill composite #27 respectively.

As the same patient was asymptomatic with relation to 17 during the initial visit and due to financial constraints, she deferred the endodontic treatment. However, she developed severe pain in the upper right back tooth region of the jaw after ten days. The patient complained of lancinating pain, which was intermittent, non radiating, aggravated on mastication, cold foods, and relieved on taking medication, and there was no associated swelling #17. The clinical examinations revealed deep occlusal caries wrt. maxillary right second molar which was tender on percussion [Table/Fig-5]. Vitality testing of the involved tooth showed lingering pain to cold test and premature response to electric pulp tester (SybronEndo, Orange, CA). Based on the findings, a diagnosis of symptomatic irreversible pulpitis with symptomatic apical periodontitis was made. The root canal treatment procedure was explained, and informed consent was taken. Preoperative radiographic evaluation revealed atypical root canal anatomy. Careful periodontal probing from mesial to distal side on the palatal aspect revealed a concavity on palatal surface and the probe dipped in the centre of palatal surface indicating a furcation. On either side of this concavity, two contours were appreciated hence the clinical examination confirmed two palatal roots. The tooth was anaesthetised with a posterior superior alveolar nerve block with 2% lignocaine (Astra Zeneca Pharma India Limited, Bangalore, India) and isolated with a rubber dam. Following access opening, based on the clinical experience gained from the previous tooth #27 and slightly deviated location of the palatal canal, the access cavity was modified from conventional triangular

to trapezoidal shape to achieve straight-line access for all canals [Table/Fig-6]. The second palatal canal orifice was explored with the aid of a DG-16 explorer (Hu- Friedy, USA), and its presence was confirmed with a dental operating microscope at 5X magnification (Labomed Dental Microscope Prima DNT, USA). It was found mesial to the usual location of the palatal canal [Table/Fig-8]. The mesio-palatal root showed moderate apical curvature towards the distal root, while the distopalatal root was relatively straight. The distance between the two palatal canal orifices was more trapezoid formed upon joining the imaginary lines connecting the four orifices was wider on the palatal side and narrower on the buccal side. The same treatment protocol was followed as in case report one [Table/Fig-7a-c]. After one year, the clinical and radiographic follow-up revealed that the patient was asymptomatic and periapical tissues were healthy [Table/Fig-8].

DISCUSSION

Successful root canal treatment depends on thorough biomechanical instrumentation and three-dimensional obturation of the entire pulp space. Undetected extra roots or canals are recognised as a significant reason for the failure of root canal treatment [1,2]. Maxillary second molars have the most complicated root canal systems [3]. Kim Y et al., reported that in maxillary second molars

4.63% had one root, 10.72% had two roots, 82.7% had three roots, and 5.6% had four roots [4]. Four rooted molars with double palatal roots were reported to occur in 1.1 to 1.5% of maxillary second molars [5,6]. The bilateral occurrence of this phenomenon has also been documented [7].

In the present case, owing to the anatomical location of maxillary second molars and impaction of the third molar onto the roots of second molars, the unusual anatomy was not appreciable on a radiograph. Therefore, the concept of the narrow field of view CBCT provided a three dimensional (3D), low-radiation/high-resolution solution to assist successful endodontic diagnostic and treatment problems in case of variations in tooth anatomy [8,9].

With regard to tooth no 27, the extra root was successfully diagnosed and treated with the assistance of CBCT. Matherne RP et al., researched the benefit of CBCT imaging in endodontic treatment; they concluded that CBCT images always identified a greater number of root canal systems than digital images [10].

Purushotham M and Sahoo H treated a maxillary molar with the aid of a dental operating microscope and careful exploration of the pulp chamber with ultrasonic tips. Upon locating a bleeding point CBCT was taken to rule out any further complex anatomy similar to the present case report [11].

CBCT slices revealed four distinct roots with four canals. Moreover, mesiobuccal and distobuccal canals were relatively closer than the mesiopalatal and distopalatal canals. Thus, the box formed by joining the imaginary lines connecting the four orifices was wider on the palatal side, giving a trapezoidal shape [12]. A similar wider location of palatal orifices than palatal orifices was observed by Alani AH, Patel S and Patel P [7,13] Carlsen O and Alexandersen V classified these teeth according to the side of the crown with which the accessory palatal root is associated [14]. Hence according to this classification, this case belongs to radix mesiolingualis- the accessory root has an affinity to the pronounced mesiopalatal part of the crown. According to Ahmed HMA et al., the root canal configurations are depicted as 427 Mesio-buccal (MB)1 Disto-buccal (DB)1 Mesio-palatal (MP)1 Disto-palatal (DP)1, 417 MB1 DB1 MP1 DP1, respectively [15].

Not all scenarios need CBCT imaging. Al Qahtani A et al., published a case report describing the retreatment of maxillary second molars with two palatal roots. As the preoperative radiograph revealed four roots, they performed retreatment based on anatomic guide lines [16]. By relying on the experience and use of magnification, such variations could be treated successfully. The same was followed in case of tooth 17. Magnification aids like dental operating

microscopes and loupes help to locate anatomic aberrations better by improving visualisation [13]. Thus precise access cavity and diagnostic aids such as dental operating microscope eliminate many potential problems such as missing additional canals and provide a better insight into root canal anatomy.

CONCLUSION(S)

Any variations in root canal morphology can be identified with the recent innovations in diagnostic and operating aids. Anatomical deviations can occur in any tooth; therefore, clinicians should anticipate these variations and utilise all the available diagnostic tools to manage them.

Effect of nonthermal atmospheric plasma on the shear bond strength of composite resin after using different tooth-whitening systems: An *in vitro* study

Bolla Nagesh, Kommineni Harika Chowdary, Praveen Kumar Gali, Tammineedi Sravanthi, Lakshmi Bhavani Potru, Aameena Banu Mayana

Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, India

Abstract

Aim: We aimed to evaluate the effect of nonthermal atmospheric plasma (NTAP) on the bond strength of composite resin after using different tooth-whitening systems.

Methods: Eighty maxillary central incisors ($n = 80$) were divided into two groups based on the tooth-whitening procedure used – Group 1: bleaching (Pola Office, USA), Group 2: microabrasion (Opalustre, Australia). The samples were subdivided into four groups depending on the surface treatments – Group A: control (no surface treatment), Group B: plasma, Group C: antioxidant (sodium ascorbate), and Group D: buffering agent (sodium bicarbonate). After the surface treatments, the specimens were stored in artificial saliva for 24 h and composite resin was bonded to the labial surface of the teeth perpendicular to the long axis. The samples were then subjected to shear bond strength test under the universal testing machine.

Statistical Analysis: The results received from shear bond strength analysis were subjected to statistical analysis using a two-way ANOVA test, independent *t*-test, and Tukey's multiple *post hoc* tests. The *P* value set was <0.05 .

Results: The highest mean bond strength value was seen in Group 2B (NTAP treatment after microabrasion) followed by Group 1B (NTAP treatment after bleaching). Mean shear bond strength values have suggested a statistically significant difference between all the other groups ($P < 0.05$) except between Groups 1A, 2A and 1D, 2D.

Conclusions: Within the limitations of the current *in vitro* study, bleaching and microabrasion followed by surface treatment using NTAP showed the highest bond strength than other groups.

Keywords: Bleaching, bond strength, microabrasion, nonthermal atmospheric plasma

INTRODUCTION

Esthetics play a vital role both socially and professionally among individuals of all age groups, thus increasing the demand for cosmetic dentistry.^[1] Some intrinsic and extrinsic enamel defects may reduce the quality of smile.^[2]

paste of 18% hydrochloric acid and flour of pumice, which involves an insignificant and unrecognizable loss of enamel.^[6,7] Immediate or delayed composite veneering or restoration is considered as the next minimally invasive treatment in certain clinical scenarios when the above tooth-whitening procedures do not give a satisfactory result. Despite being conservative approaches, bleaching and microabrasion resulted in the alteration of surface topography of enamel that might reduce the bond strength of direct or indirect veneers.^[11] Several researchers have postulated the presence of active chemicals or free radicals as one of the reasons for reduced bond strength followed by bleaching.^[8] Surface treatment either with a biocompatible and neutral antioxidant such as sodium ascorbate or a buffering agent before bonding may reverse this effect and neutralize the acidic pH.^[9,10] In the past few years, nonthermal atmospheric plasma (NTAP) has been widely experimented in biomedical and dental applications, attributed to its ability in altering the surface characterization and enhancing the adhesion.^[11]

The current study evaluated the effect of NTAP on the bond strength of composite resin after using different tooth-whitening systems.

METHODS

Specimen preparation

Eighty intact permanent maxillary central incisors, freshly extracted due to periodontal diseases, were selected for the present study. Preference was given to teeth with intact crowns regardless of the root structure. The sample size was calculated using Raosoft online^[12] (<http://www.raosoft.com/samplesize.html> accessed on December 2019) sample size calculator, and the power of the study set was 80%. The teeth with visible fractures, cracks, teeth not stored in any media, and teeth with developmental defects were excluded from the study. The collected teeth were stored in distilled water containing 0.2% thymol solution (Chemigens Research and Fine Chemicals, Mumbai, India). The teeth were then embedded in self-cure acrylic (DPI products, India) resin blocks till cemento-enamel junction. The labial enamel surfaces of all samples were cleaned using a prophylactic paste (DPI Propol, India) with a rubber cup attached to slow-speed handpiece (Yoda Greentech, Gujarat, India) to remove any surface debris.

Nonthermal atmospheric plasma jet apparatus

Compressed helium gas with a pulse head of 2 GHz at 3.25 standard liter was used to generate the plasma jet. The delivery pressure was maintained <2 pascals with a mean power of 2 Watt. Each application was carried for a total period of 15 s in the installments of 5 s each with a rest period of 5 s in between. The distance between the

applicator tip and the tooth surface was maintained at 5 mm. All the parameters were controlled by a microwave generator-connected module (Acxys Smart Systems, Germany). The temperature changes at the enamel surface were monitored using a thermocouple and found to be in the range of 27°C–29.4°C which is well tolerated by dental pulp.^[13] All the plasma exposures were done in an isolated chamber to prevent any possible environmental contamination.

Experimental procedure

The teeth were randomly divided into two main groups depending on the tooth-whitening system: Group 1 – bleaching and Group 2 – microabrasion. In Group 1, the labial surface of the teeth was blot dried using blotting paper. Contents from the Pola Office syringe (SDI limited, Australia) containing 35% hydrogen peroxide were released into the pot containing bleach powder (73.26% thickeners, 26.2% catalysts, 0.04% dye, and 0.5% desensitizing agents) and mixed immediately using a brush applicator until the gel is homogeneous. A uniform layer of gel was applied to the labial surface of the teeth and left for 6–8 min [Figure 1a] and was later rinsed off using distilled water.

In Group 2, a fine grit (TC-11EF/20–30 μm) water-cooled diamond bur (Mani, Inc., Japan) was used to superficially abrade the labial surface in two to three gentle strokes to initiate microreduction. A plastic White Mac Tip (Ultradent, USA) was attached to the Opalustre syringe and a uniform layer was applied to the labial surfaces. A slow-speed handpiece (Yoda Greentech, Gujarat, India) was used at 250 RPM, with the Opal prophycups (Ultradent, USA) [Figure 1b] directly on the enamel surfaces for 60 s and later rinsed off with distilled water.

Both the groups were further divided into four subgroups depending on the surface treatment performed:

- Group A: Control group – No surface treatment was done (1A and 2A)
- Group B: Plasma group – The labial surface of the samples was subjected to NTAP for 15 s [Figure 1c] (1B and 2B)
- Group C: Antioxidant group – The labial surface of the teeth was treated with 10% sodium ascorbate liquid (Avi Chem Industries, India) for 30 s by applying gentle pressure using a brush and then rinsed off [Figure 1d] (1C and 2C)
- Group D: Buffering group – The labial surface of the teeth was treated with 10% sodium bicarbonate liquid (Avi Chem industries, India) for 30 s by applying gentle pressure using a brush and then rinsed off [Figure 1d] (1D and 2D).

All the specimens were stored in artificial saliva for 24 h at 37°C in an incubator (Nabertherm lab incubator, India).

(d) Antioxidant solution and buffering solution. (e) Contact angle measurement. (f) Instron machine testing for shear bond strength

Figure 2: Comparison of interactions of two main groups (1 and 2) and four subgroups (A, B, C, and D) with shear bond strength

Contact angle measurement

Six of the samples with near-flat enamel surface from each group were selected and contact angle has been evaluated with the help of a goniometer (Rame-Hart Contact angle goniometer). Bidistilled water was used as the contact medium in the process [Figure 1e].

Composite restoration

Self-etch adhesive (Single Bond Universal adhesive, 3M) was applied on the labial enamel surfaces of all the above specimens as suggested by the manufacturer using an applicator tip. The first coating of the bonding agent was applied, left for 10 s, and was air-dried gently to allow the evaporation of any excess material. The second coat of bonding agent was applied in the same manner and photo-polymerized (LED Curing Light, Woodpecker – 5W high power blue light LED, 420–480 nm, 650 mW/cm²–800 mW/cm²). A custom-made cylindrical plastic matrix of 2 mm diameter and 2 mm height was used

as a mold to pack the composite material. The plastic mold was placed on the labial surface of the tooth perpendicularly followed by incremental layering (1 mm each) of composite material using a plastic filling instrument (Ivoclar, USA). Each increment was photo-polymerized for 20 s. After polymerizing, the plastic matrix was separated carefully. All the specimens were stored in artificial saliva for 24 h at 37°C in an incubator (Nabertherm lab incubator, India) to simulate the oral environment after the composite restoration.

Shear bond strength test

After completion of incubation, the shear bond strength of composite to the tooth surface was determined using a Universal Testing Machine (Instron Universal Testing Machine, Model 8801). A chisel-edge plunger was mounted onto the movable crosshead of the testing machine with the leading edge aimed at the composite and labial surface interface at a crosshead speed of 1 mm/min. The force required to de-bond the restorative material was

measured, and the shear bond strength was calculated by dividing the peak load values and the restorative material base area (N/mm^2) [Figure 1f].

RESULTS

The results obtained were then analyzed statistically using the Statistical Package for the Social Sciences (SPSS) (SPSS software version 20.0; SPSS Inc., Chicago, IL, USA). Data were analyzed using a two-way ANOVA test for overall significance, independent *t*-test, and Tukey's multiple *post hoc* tests for inter- and intragroup comparison, respectively. The highest mean bond strength values were seen in Group 2B (microabrasion followed by plasma), followed by Group 1B (bleaching followed by plasma). The lowest mean bond strength values were seen in Group 2A and Group 1A [Table 1 and Figure 2]. Mean shear bond strength values have suggested a statistically significant difference between other groups ($P < 0.05$) except between Groups 1A, 2A and 1D, 2D.

DISCUSSION

Plasma is portrayed as the fourth state of matter and is extremely a reactive material comprising strong electric field, radicals, and charged particles.^[14] NTAP generated at atmospheric pressure, when used as an adjuvant increased the outcome of the bonding technique. For the above reasons, it has recently gathered attention not only in industrial sector but also in the medical and dental fields.^[15]

Esthetic reconstructions, laminate and composite veneers, are often necessary after the tooth-whitening procedures.^[16] Tittley *et al.* explained the primary mechanism of bleaching as ionic dissociation of hydrogen peroxide and increased formation of free radicals such as nascent oxygen and the hydroxyl radical on the enamel surface.^[17] Although bleaching has proven to be a safe and effective treatment, it may present specific antagonistic effects on the enamel, such as surface morphological changes, compositional changes, alterations in the surface microhardness, and surface roughness.^[18] Furthermore, there is evidence

that tooth bleaching led to a reduction in bond strength of composite resin applied to previously bleached enamel.^[17] Glasspole *et al.* stated that the reduced bond strength was due to the prevention of resin infiltration and polymerization because of oxygen-free radicals.^[19] Various additional surface treatments after subjecting the tooth to tooth-whitening procedures were indicated lately to reverse the effect of such methods on the bonding properties of the tooth.^[20]

It was found that NTAP increased the bond strength at the dentin-composite interface by 60%.^[21,22] This interface-bonding enhancement was reported to significantly improve composite performance, durability, and longevity.^[22] In the current study, a significant increase in the bond strength was seen in the groups that were subjected to plasma irrespective of the tooth-whitening procedure used. Plasma enhances the hydrophilicity of the tooth surface, surface energy, and wettability and changes the chemical structure of exposed collagen fibrils by temporarily uncovering the functional groups and partially dispersing them.^[23] In case of dentin, it has been proven that the surface modification plays a lesser role compared to alteration of the surface chemistry due to the presence of higher organic content and more collagen fibrils. In the present study, since the evaluated area is mostly on the enamel, alteration of surface properties seems to play a major role than surface chemistry which is evident by reduced contact angle. Plasma-treated samples have shown the lowest contact angle compared to all the study groups^[23] [Figure 1e].

When NTAP was used along with hydrogen peroxide, increased molecular breakdown and superior bleaching ability were observed.^[24,25] However, there is minimal or no literature evaluating the effect of plasma on the bond strength after treating the tooth surface with bleaching or microabrasion. The present study evaluated the same.

It was found that application of plasma after microabrasion significantly improved the bond strength compared to plasma treatment after bleaching. The superior bond

strength might be due to the nonselective etching, enamel demineralization, and increased surface roughness by the aggressive hydrochloric acid. The further application of plasma enhanced the adhesive-tooth bond strength.^[26] However, the efficacy of plasma is reduced due to the residual free radicals after bleaching resulting in inferior bond strength compared to microabrasion.^[19]

Several authors postulated that the application of antioxidants on the bleached tooth surface caused the reversal of detrimental effects.^[27-29] In the current study, the use of sodium ascorbate showed increased bond strength values compared to the control group similar to a previous study conducted by Kaya *et al.*^[30] This might be due to the potential of antioxidant agents to prevent the interference of residual radicals with the polymerization of adhesives, which in turn showed the improvement of the bond strength of resin composites to bleached enamel.^[31,32] After the bleaching procedure, increased free radicals are effectively reduced by antioxidant treatment resulting in better bond strength compared to the control group. However, after the microabrasion procedure, the released free radicals are minimal and also the available collagen content is more compared to bleached tooth surface due to the greater surface depth. Further attributed to the collagen-cross-linking ability of the antioxidants, in the current study, the bond strength of the composite in Group 2C (microabrasion and antioxidant) is greater than Group 1C (bleaching and antioxidant).

On the other hand, various studies evaluated the effect of surface treatment using a buffering agent on the bleached enamel and its influence on composite resin bonding.^[10] It was reported that there was an improvement in the bond strength values after using a buffering agent. The outcomes of the present study are in conjunction with the previous literature stating that the application of a 10% sodium bicarbonate solution after bleaching procedure could be an alternative prerestorative treatment.^[33] The mechanism of action of sodium bicarbonate built on its high pH (approximately 8.67) can disrupt the peroxide molecule and result in its decomposition and inactivation.^[10] Buffering agent in combination with microabrasion performed better than bleaching. This is evident as there is no much reduction in the pH after bleaching procedures as compared to microabrasion revealing the effectiveness of buffering agent. However, there is no statistically significant difference in the bond strength between both the groups (Group 1D and 2D).

The plasma-treated group showed the best results which could be due to the improvement in the interface properties and modification of the tooth surface, thus increasing the tooth/adhesive interfacial bonding. Still, further studies are required to clinically evaluate the effect of plasma on

bond strength, microabrasion, and bleaching in the near future. It is of valuable interest to know if the application of plasma after using antioxidant or buffering agent enhances the bonding further in the upcoming studies.

CONCLUSIONS

Within the limits of the study, it can be concluded that

1. Irrespective of the tooth-whitening procedure performed, surface treatment using plasma showed a significant increase in the mean bond strength values
2. No significant difference in the mean bond strength values was seen between bleaching and microabrasion without any surface treatment
3. Application of sodium ascorbate and sodium bicarbonate showed an increase in mean bond strength values compared to control groups.

Department of Conservative Dentistry and Endodontics, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, ¹Department of Chemistry, Indian Institute of Space Science and Technology, Thiruvananthapuram, Kerala, India

Abstract

Aim: The aim of this study was to evaluate the effect of nonthermal atmospheric plasma (NTAP) on the bond strength of epoxy resin-based and bioceramic root canal sealers.

Materials and Methods: Freshly extracted forty ($n = 40$) single-rooted mandibular premolar teeth were divided into four groups ($n = 10$) based on the sealer used and NTAP application – Group 1: Epoxy resin-based sealer (AH Plus) without NTAP application, Group 2: Epoxy resin-based sealer (AH Plus) with NTAP application for 30 s, Group 3: Bioceramic sealer (BioRoot RCS) without NTAP application, and Group 4: Bioceramic sealer (BioRoot RCS) with NTAP application for 30 s. After NTAP application in Groups 2 and 4, all the samples were obturated using sealers according to their grouping protocols. Two-millimeter slices were obtained from each sample using hard tissue microtome, which were subjected to push-out bond strength (PBS) under the universal testing machine. Data were subjected to statistical analysis using one-way analysis of variance followed by the Post hoc tukey test. The level of statistical significance was set at $P < 0.05$.

Results: The PBS values were observed to be significantly higher in bioceramic sealer with NTAP application (Group 4) followed by epoxy resin-based sealer with NTAP application (Group 2).

Conclusion: NTAP application enhanced the PBS of bioceramic (BioRoot RCS) and epoxy resin-based (AH Plus) sealers compared to their control groups.

Keywords: AH Plus sealer; bioceramic sealer; nonthermal atmospheric plasma; push-out bond strength

INTRODUCTION

Successful endodontic treatment is dependent on the meticulous cleaning of the root canal system, the eradication of pathogenic microorganisms, and a three-dimensional filling of root canal space with an inert root canal filling material and attaining a fluid tight seal to prevent the ingress of microorganisms

from the oral cavity and its spread to the periapical tissue.^[1]

Root canal sealers are used as a thin tacky paste which functions as a lubricant and luting agent during obturation allowing the core obturation material such as gutta-percha or other rigid materials to slide in and forms a fluid tight seal within the root canal. Sealers can fill voids, lateral canals, and accessory canals where core obturation materials cannot infiltrate. If the sealer does not perform its function, microleakage may cause endodontic treatment failure through the clinically undetectable passage of bacteria, fluids, molecules, or ions between the tooth and

Garlapati, *et al.*: Effect of NTAP on bond strength of root canal sealers

the restorative material. A great variety of endodontic sealers are available commercially, and they are divided into different groups according to their chemical composition.^[2]

Traditionally used root canal sealers are zinc oxide eugenol, calcium hydroxide, and glass ionomer-based sealers. Newer root canal sealers such as epoxy resin and bioceramic based are being developed to provide the improved properties. AH Plus sealer (Dentsply Maillefer, Ballaigues, Switzerland) is an epoxy resin-based sealer which contains diepoxide, calcium tungstate, N, N-dibenzyl-5-Oxanonane-diamine-1,9 TCD-diamine-1-adamantane amine, and zirconium oxide. AH Plus is a widely used sealer for root canal filling due to its acceptable physical properties, low solubility, disintegration, apical sealing ability, good adhesion, antimicrobial action, and good biological properties.^[3] Baechtold *et al.* evaluated the adhesion capability of two sealing cement, namely MTA Fillapex and AH Plus, and reported that AH Plus sealer has greater adhesion than the MTA Fillapex.^[4]

Bioactive endodontic sealers have been developed to improve the quality of root canal obturation. BioRoot RCS (BC) (Septodont, St. Maur-des-Fosses, France) is the newest development of a bioceramic sealer. The powder mainly consists of tricalcium silicate, povidone, and zirconium dioxide. The liquid is an aqueous solution of calcium chloride with polycarboxylate. Contemporary studies on BC sealer have documented its several adequate characteristics, including its adhesive property, low dimensional change, proper radiopacity, and low solubility.^[3]

Adhesion and penetration are two important aspects to be considered in sealer selection. Studies have shown that bond strength and sealer penetration may be affected by pretreatment of root canal walls and by the type of sealer used. These procedures change the physical conditions of dentin by removing the smear layer, thereby opening the dentinal tubules and increasing the wettability of root canal dentin.^[5]

Recently, the possibility to generate nonthermal atmospheric plasma (NTAP) has enabled extending plasma applications to the treatment of root canal surfaces. The interest in plasma applications in dentistry is due to its several unique advantages over conventional approaches, such as the ability to penetrate into small and irregular root canal recesses and achieve bacterial decontamination without using potentially dangerous chemicals.^[6] NTAP has improved the bond strength between dentin and adhesive materials.^[7]

Previous studies have demonstrated that NTAP was effective and efficient in sterilization of endodontic instruments, other surgical instruments, elimination of persistent,

nonaccessible biofilms, sterilization, and thorough disinfection of root canals. Raymond E. J. *et al.* used a plasma needle to observe the interactions between NTAP and dental tissues and concluded that plasma treatment allows cleaning of irregular and narrow channels and it is a novel tissue-saving technique. NTAP was an effective source of free radicals and have the property of eradicating microbial disinfection without causing destruction of the tissue. Whittaker *et al.* suggested that sterilization of surgical instruments with NTAP decreases the cross contamination during endodontic treatment.^[8]

Lu *et al.* used a reliable and user-friendly plasma jet device, which could generate NTAP, and it is directed into the root canal for disinfection without causing any painful sensation.^[9] Pan *et al.* investigated the feasibility of using NTAP in root canals infected with *Enterococcus faecalis* biofilms and concluded that NTAP was highly efficient in disinfecting the *E. faecalis* biofilms during root canal treatment.^[10]

To the best of our knowledge, there are no studies in the literature reporting the effect of NTAP on the bond strength of epoxy resin-based (AH Plus) and bioceramic (BioRoot RCS) root canal sealers. Hence, the main purpose of the present *in vitro* study was to evaluate and compare the effect of NTAP application on the push-out bond strength (PBS) of epoxy resin-based and bioceramic root canal sealers.

MATERIALS AND METHODS

Specimen preparation

Freshly extracted forty ($n = 40$) single-rooted mandibular premolar teeth were selected. Crowns were decoronated below the cemento-enamel junction using a low-speed hand piece, so that the lengths of all roots were adjusted to 15 mm. Patency of each root canal was checked using a size 10 K-file (Dentsply Maillefer, Ballaigues, Switzerland) and working length was established 1 mm short of the apex.

Cleaning and shaping procedures were performed using ProTaper Gold (Dentsply Sirona, USA) rotary nickel-titanium instruments. Canals were irrigated with 2 mL of 5.25% sodium hypochlorite (NaOCl) (Prime Dental Products, Maharashtra, India) between each file change followed by irrigating with 2 mL of 17% ethylenediaminetetraacetic acid (MD-Cleanser, META Biomed, Korea) to remove the smear layer formed after instrumentation. Root canals were finally flushed with 5 mL of distilled water and dried with paper points. All the samples ($n = 40$) were divided into four groups ($n = 10$):

- Group 1 ($n = 10$): Epoxy resin-based sealer (AH Plus) without NTAP application
- Group 2 ($n = 10$): Epoxy resin-based sealer (AH Plus) with NTAP application

- Group 3 ($n = 10$): Bioceramic sealer (BioRoot RCS) without NTAP application
- Group 4 ($n = 10$): Bioceramic sealer (BioRoot RCS) with NTAP application.

Nonthermal atmospheric plasma application

After cleaning and shaping of samples in Group 2 and Group 4, they were subjected to NTAP application. This was conducted at the Department of Chemistry, Indian Institute of Space Science and Technology, Thiruvananthapuram, Kerala. A glass reactor was used for NTAP application. This glass reactor consists of a 5-cm diameter and 30-cm long tube, evacuated by a mechanical pump, down to pressures lower than 2 Pa. Gas was allowed to fill the glass reactor up to a pressure of 10 Pa. NTAP was generated within the glass cylinder under vacuum by the action of an induced magnetic field from the current passing through an electrical coil surrounding the cylinder. Surfaces of the samples were treated using helium–argon gas at 60 W for 30 s. At the end of the process, radiofrequency was turned off before the samples were exposed to air.

In the control and experimental groups (after NTAP application), all the samples were obturated using the single-cone technique with size 25/.08 gutta-percha points (Dentsply Maillefer, Ballaigues, Switzerland) using AH Plus in Group 1 and Group 2 and BC sealer in Group 3 and Group 4, respectively. The roots were mounted on the self-cure acrylic resin cylinders and were subjected to hard tissue microtome (SRM Institute of Science and Technology, Kattankulathur, Chennai) to obtain 2-mm slices from the middle third of the root from each sample.

Push-out bond strength test

The obtained 2-mm slices were subjected to PBS test, and loading was performed using a universal testing machine (Instron Servohydraulic Testing System, Mechanical Department, GITAM, Visakhapatnam). The samples were placed on a base of a metal slab of universal testing machine to allow the free movement of the plunger. The compressive load was applied by exerting a downward pressure on the surface of the test material in each sample, with the Instron probe moving at a constant speed of 1 mm/min. The plunger size of 1 mm had a clearance of approximately 0.2 mm from the margin of the dentinal wall to ensure contact only with the test materials. The maximum force which was applied to materials at the time of dislodgement was recorded in newtons. The PBS in megapascal (MPa) was calculated by dividing this force (N) by the surface area of the test material where $N/2p \times r \times h$, p is the constant 3.14, r is the root canal radius, and h is the thickness of the dentin slice in millimeters.

Statistical analysis

Data were entered in MS-Excel and analyzed in Version 21.0 (IBM Corp. Chicago, USA). Shapiro–Wilk test was applied to find the normality. Descriptive statistics were represented with mean and standard deviation (SD). 95% confidence intervals were calculated. One-way analysis of variance, followed by Post hoc tukey test, was applied to find significance. $P < 0.05$ was considered as statistically significant.

RESULTS

Table 1 shows the mean values and SD of the PBS (MPa) of all the groups. Results shown that NTAP-applied samples, i.e., Group 2 and Group 4, had a statistically significant increase in bond strength, more than twice that of their respective control groups, i.e., Group 1 and Group 3 ($P < 0.05$). Bioceramic sealer (BioRoot RCS) showed significant bond strength values compared to AH plus sealer without NTAP application ($P < 0.05$).

DISCUSSION

The aim of endodontic therapy is not only elimination of microorganisms by cleaning and shaping of the root canal but also to ensure that the root canal system to be fluid free and that a single-block configuration is created that seals hermetically the root canal space. The major function of a root canal sealer is to fill imperfections and increase adaptation of the root canal filling material to the canal walls, failing which the chances of leakage and failure increase.

The ability of the PBS test is to evaluate the bonding strength surpasses that of other tests because it generates parallel fractures in the interfacial area of dentin bonding. However, a limitation of the PBS test is that it creates nonuniform stress distribution. In the present study, this limitation was prevented using 2-mm thick slices.^[3]

Root canal disinfection using NTAP can be considered as a special type of decontamination because of its importance in the endodontic procedures for a successful outcome. It has been reported that bacteria can enter dentinal tubules as deep as 500–1000 μm . NTAP has a capability of reaching deep into the complex root canal, i.e., up to 800 μm . NTAP creates reactive oxygen species, causing serious damage to microorganisms through irreversible oxidation of cell components. There is an unique advantage of direct contact with the bacteria using NTAP, which is not possible with conventional methods.^[11]

With respect to NTAP application, bioceramic sealer (Group 4) showed higher bond strength than epoxy

resin-based sealer (Group 2). Lehman *et al.*^[6] reported that without NTAP application, the intertubular areas appear slightly roughened on etched dentin, smear plugs were removed from the tubules, and the collagen network is visible within the tubules and in the intertubular areas. With NTAP application, no collagen fibers are visible on this surface and the orifices of dentinal tubules appear irregularly enlarged, which results in the better penetration of root canal sealer into the dentinal tubules and could ensure higher mechanical retention of the root canal filling materials. This might be the possible reason for the increased PBS values of Groups 2 and 4 twice that of control groups, i.e., Group 1 and Group 3, in the present study.

The application of NTAP into the root canal walls provides a better bond strength while using bioceramic-based root canal sealers for obturation procedure.^[12] Hence, NTAP can be used as an adjuvant during endodontic treatment to increase the adhesion property of root canal sealers which might result in a successful outcome.

In the present study, compared to epoxy resin-based sealer (Group 1), bioceramic sealer (Group 3) showed higher bond strength. This may be attributed to the true self-adhesive nature of bioceramic sealer, which forms a chemical bond (through the production of hydroxyapatite during setting) with dentin. Moreover, it is hydrophilic and possesses low contact angle allowing it to spread easily over the root canal walls providing adaptation and good fluid tight seal.^[13] The results are in accordance with a previous study done by Ana Carrillo-Varguez AG *et al.* (2017)^[14] who reported that BC sealer with single-cone technique performed better adhesion than AH Plus to root canal dentin.

Srivastava *et al.* from their study observed that BioRoot RCS showed better bond strength to root dentin compared to AH Plus after using different irrigating solutions. BioRoot RCS showed better bond strength to root dentin compared to AH Plus probably due to setting reaction of the bioceramic-based sealer. It absorbs water from the dentinal tubules and forms calcium silicate hydrogel and hydroxyapatite compound. The hydroxyapatite which is present in the sealer undergoes a continuous process of crystal growth and binds chemically with the dentin. Being resin free, it is capable of flowing into the dentinal tubules with no shrinkage and provides excellent adhesion

to dentin and gutta-percha and its ability to seal auxiliary canals.^[15] A study done by Dayanand Chole *et al.*^[3] reported that BioRoot RCS showed the highest bond strength than AH Plus and MTA Fillapex due to its true self-adhesive nature. According to Han and Okiji,^[16] the formation of a tag-like structure was suggested to be responsible for the BC sealer sealing ability and their bond strength to dentin.

Sagsen *et al.* (2011)^[17] evaluated the bond strength of two new calcium silicate-based and AH Plus endodontic sealers and found that AH Plus sealer had higher PBS values than MTA Fillapex because of the better flow and sealing ability of AH Plus sealer. In a study by Kumar *et al.*, results revealed that the dislocation resistance of AH Plus to root canal dentin was significantly decreased by the use of NaOCl as a final irrigant. Reversal of the compromised PBS and also improved adhesion of epoxy resin-based sealer (AH Plus) to NaOCl-treated dentin was significantly increased when proanthocyanidin and bamboo salt were used as final irrigating solutions. Epoxy resin-based sealers (AH Plus) produces a better seal in the root canal, as they do not shrink, rather they expand and seal the root canal.^[18]

In a study done by Huang *et al.*, bioceramic root canal sealers have shown excellent flow and appropriate film thickness, as well as favorable properties, including high calcium ion release, proper radiopacity, low dimensional change, and low solubility. From their observations, they concluded that BC sealers showed superior wetting and adhesion properties to the root canal dentin. BC sealers having excellent flow would obturate irregular spaces and penetrate into dentinal tubules, thus enhancing the seal between the root canal surface and sealers, this might contribute to the increased bond strength value of BC sealer in the present study.^[19]

As per the literature, the current *in vitro* study is the first one to evaluate and compare the effect of NTAP on the PBS of epoxy resin-based (AH plus) and bioceramic (BioRoot RCS) root canal sealers. However, this being an *in vitro* study, it cannot mimic the *in vivo* situation. The application of the NTAP in an *in vivo* condition is yet to be evaluated. For NTAP to reach the clinical use, future research activities should involve increasing numbers of dentists and move towards animal testing; on this path, assessing the safety of NTAP treatments and employing plasma sources that are realistically applicable in a clinical environment will be inevitable steps.

Table 1: Mean push-out bond strength value of four different experimental groups

Group	n	Minimum	Maximum	Mean	SD	P
GROUP 1	10	1.90	4.31	3.40	0.72	<0.001
GROUP 2	10	4.94	7.24	6.13	0.84	
GROUP 3	10	3.25	4.62	3.90	0.45	<0.001
GROUP 4	10	8.43	9.67	9.04	0.41	

CONCLUSION

Within the limitations of this *in vitro* study, NTAP application significantly increased the PBS values of epoxy resin-based (AH Plus) and bioceramic (BioRoot RCS) root canal sealers. Bioceramic sealer with and without NTAP

application has shown higher PBS values than that of epoxy resin-based sealer.

ABSTRACT

Background: To maintain the integrity of the interface between root canal filling and radicular dentin an ideal endodontic biomaterial should have good adhesion. This study was aimed to evaluate the bond strength and tubular penetration of modified bioceramic materials by indirect ultrasonic activation.

Materials and Methods: In the present *in vitro* experimental study, 120 coronal root slices of 2 mm were prepared from mandibular premolars and randomly divided into six groups ($n = 20$) in accordance to placement techniques: Group I: Nano Biodentine-manual, Group II: CaCl_2 modified ProRootMTA-manual (MM), Group III: Biodentine-manual, Group IV: Nano Biodentine: Ultrasonic, Group V: CaCl_2 modified ProRootMTA-ultrasonic, and Group VI: Biodentine-ultrasonic (BDU). The samples were kept in humidifier for 4 days at 37°C and push out bond strength, sealer penetration were evaluated using an universal testing machine and confocal laser scanning microscope respectively. Data were subjected to statistical analysis using SPSS software by using One-way ANOVA for overall significance and Tukey's multiple *post hoc* test for intergroup comparison ($P < 0.05$).

Results: Highest push out bond strength and greater tubular penetration were observed with Group VI (BDU), while the lowest bond strength and tubular penetration were associated with Group II (MM).

Conclusion: Within the limitations of current study it was observed that Biodentine with indirect ultrasonic activation has resulted in highest pushout bond strength among all the study groups.

Key Words: Confocal laser scanning microscopy, mineral trioxide aggregate, nanomaterials, tricalcium silicates

INTRODUCTION

Endodontic materials should be resistant to dislocating forces such as functional pressure or condensation for good long term prognosis. Since past decade there has been a greater utilization of bioceramic materials in endodontics. Mineral trioxide aggregate (MTA), a calcium silicate based hydraulic cement (CSC) is widely used for perforation repair,

root-end filling, pulpotomy, apexification and regenerative procedures. MTA has several desirable properties such as biocompatibility, superior sealing ability, and the ability to set in the presence of moisture and wet environment. However, MTA possesses some notable shortcomings such as long

setting time, poor immediate washout resistance and difficult handling property. In few recent studies, to improve the physicochemical properties of MTA, the addition of calcium chloride (CaCl_2) to MTA^[1] with the concentration of 2%–15% has been proposed^[1] to reduce the setting time of the material^[2,3] with similar biocompatibility.^[4]

Biodentine (Septodont, Saint Maur des Fosses, France) is a more recent CSC with improved physical properties and reduced setting time as compared to MTA.^[1] Biodentine powder is mainly composed of tricalcium silicate, calcium carbonate (filler material) and zirconium oxide (radiopacifier), whilst the liquid consists of CaCl_2 (used as a setting accelerator) and a hydro soluble polymer (water-reducing/super plasticizing agent). This biomaterial is considered as a biocompatible and bioactive dentine substitute and has been indicated for coronal and radicular restorations.^[1]

Nanotechnology can be beneficial in producing and constructing advanced biomaterials with exclusive biological, chemical and physical properties.^[5] In present study Nano Biodentine (NBD) has been included to evaluate its adhesive properties compared to Biodentine.

Indirect Ultrasonic agitation has been proposed as an effective mode of increasing the packability and density of endodontic materials as well as the compressive strength of hydraulic cements.^[6]

Till date, a little information is available on the bond strength and adhesive properties of CaCl_2 modified MTA and NBD to radicular canal dentin with the indirect ultrasonic activation. This current study evaluates the push out bond strength of CaCl_2 modified MTA and NBD with manual placement and indirect ultrasonic activation techniques.

MATERIALS AND METHODS

An *in vitro* experimental study was conducted on recently extracted human mandibular premolars with single root, extracted due to periodontal and orthodontic considerations between July and September 2018 at department of conservative dentistry and endodontics, SIBAR institute of dental sciences, Takkellapadu, Guntur, and Andhra Pradesh, India. Institutional ethical clearance was obtained. The sample size was calculated using Raosoft online sample size calculator and the power of study set was 80%. The criteria for teeth selection included the

presence of single rooted teeth with canal curvature between 5° and 10° , the absence of any micro cracks on dentinal walls under stereomicroscope at 4X magnification, absence of internal and external resorption or calcification and with complete formation of root apex. Each tooth was radiographed both buccolingually and mesiodistally to detect any possible calcifications. After a thorough screening, a total of 120 samples were considered for the inclusion in this *in vitro* study.

Specimen preparation

The collected single rooted human mandibular premolars were decoronated at the cemento-enamel junction with a diamond disc (Wuxi xiangsheng industrial and trading co.) mounted on a micro motor (NSK Ti-max Nao 95LS) under water coolant. A total of 120 samples were selected, which were sectioned perpendicular to the long axis at mid coronal third of root to attain dentin discs of 2mm thickness using Isomet precision cutter (Buehler Inc). While selecting, these discs were gauged with a customized acrylic gauge for a standardized internal diameter. The root sections were immersed in 17% EDTA (Vista Dental Products, U.S.A) followed by water rinse and then in 2.5% sodium hypochlorite (PrevestDenpro Dental Products, India) each for 1 min to remove the smear layer. They were then cleansed with distilled water in an ultrasonic bath. Later, the root canal surfaces of the samples were dried with a dehydrating solution using absorbent points (Hydrol, septodont).

Experimental procedure

The root sections were randomly assigned into 6 groups:

- Group I: Nano Biodentine-manual (NBDM) ($n = 20$)
- Group II: ProRoot MTA modified with CaCl_2 -manual (MM) ($n = 20$)
- Group III: Biodentine-manual (BDM) ($n = 20$)
- Group IV: Nano Biodentine-ultrasonic placement (NBUDU) ($n = 20$)
- Group V: ProRoot MTA modified with CaCl_2 -ultrasonic placement (MU) ($n = 20$)
- Group VI: Biodentine ultrasonic placement (BDU) ($n = 20$).

Manipulation

MTA (DentsplyMaillefer, Ballaigues, Switzerland) and Biodentine (Septodont, Saint Maur des Fosses, France) were manipulated according to the manufacturer's instructions. To achieve uniformity while manipulation all the materials used in present

study has been mixed using a capsule attached to a mechanical activator (Ultramat-2). MTA and 5% Calcium chloride were mixed in a 3:1 proportion as previously suggested.^[1] Nano Biodentine (NBD), obtained by Ball milling of Biodentine in a zirconia ball-mill machine (Gold Belt Global) for 24 h. The particle size of final product has been evaluated and confirmed to be in the range of 2.3–5 nm by Dynamic light scattering (Department of Biochemistry, Osmania University, Hyderabad). To enable the condensation of the materials, the specimens were placed over a tinfoil, which was stabilized on a customized elastomeric block [Figure 1].

Measurement of setting time

All the materials were estimated for setting time as it might be the influencing factor on the bond strength, in plastic cylindrical templates by using stop watch/tachometer till the disappearance of surface gloss.

Manual condensation

The materials were then delivered into the lumen of the root canal of each specimen in groups I (NBDM), II (MM) and III (BDM) with a MTA Endo gun (DentsplyMaillefer). The specimens were obturated using a stainless endodontic plugger of size #5 which is subjected to 3.22 MPa vertical compression which is frequently evaluated and corrected by a pressure sensitive device (Department of Mechanical Engineering, AcharyaNagarjuna University, Guntur).

Indirect ultrasonic activation

After condensation of each specimen in Groups IV (NBDU), V (MU) and VI (BDU) with hand plugger, the end of the plugger remained in contact with the material while it is indirectly activated for 5 seconds with ultrasonic tip CPR 1 (Dentsply, Tulsa, United States) attached to a P5 NewtronXS™ unit (SATELEC, 4th Gen. Aceton, North America) set on its medium power setting i.e., with frequency value adjusted at 5 [Figure 2]. Excess unset material was removed gently from the surface of the specimens using the scalpel blade. The samples were wrapped in wet pieces of gauze and kept in incubator at 37° and 100% humidity for 96 h to ensure complete setting of the material.

Push out test

Ten samples from each group were evaluated for bond strength of the materials using an Universal Testing Machine (Instron Universal Testing Machine, Model 8801). The samples were mounted on a metal slab with a 1.5-mm central aperture. A cylindrical

stainless steel plunger of 1-mm diameter and operating at a speed of 1 mm/min⁻¹ was used to apply force on materials inside root slices [Figure 3]. The load applied to the material at the time of displacement was recorded in Newton and later converted to megapascals (MPa).

Figure 1: Customized elastomeric block.

Figure 2: Indirect ultrasonic activation against hand plugger remained in contact with the material.

Evaluation of mode of failure

Mode of failure was evaluated by observing under stereomicroscope at 10 X magnification. Mode of failures was identified as cohesive (within either of the filling material, dentin), adhesive (between filling material and dentin) and mixed (both cohesive and adhesive failures) [Figure 4].

Evaluation under confocal laser scanning microscope

Remaining ten samples from each group were evaluated under confocal laser scanning microscope (LSM 880, Zeiss Microscopes, Germany) to assess the extension of root filling material into dentinal tubules [Figure 5]. In order to facilitate analysis, the filling materials were labeled with Rhodamine B (Sigma Aldrich, St. Louis, MO, USA) to an approximate concentration of 0.1%. Samples were examined at 2.5 X (total magnification of 50 X) and 10 X (total magnification of 100 X) magnifications to evaluate the penetration as well as maximum depth of penetration in micrometers and images were analyzed by Ziess LSM 880 image examiner software (ZEN Blue version). For depth of penetration the point of deepest penetration has been considered and recorded in micrometers [Table 1].

Statistical analysis

Mean pushout bond strength values [Table 2] are obtained and subjected to statistical analysis using SPSS software (version 20.0; SPSS Inc., Chicago, IL, USA). One-way ANOVA test was used for evaluation of overall significance ($P < 0.05$) [Table 3] and Pair wise comparison of the groups by Tukey's multiple *post hoc* test [Table 4].

RESULTS

Box plot diagram represents distribution of

Table 1: Mean depth of penetration of bioceramic materials

Groups (n=10)	Mean depth of penetration (µm)	P
Group I (NBDM)	130.8727	<0.001
Group II (MM)	70.2865	<0.001
Group III (BDM)	190.4952	<0.001
Group IV (NBDU)	382.2743	<0.001
Group V (MU)	256.4572	<0.001
Group VI (BDU)	310.5746	<0.001

One way ANOVA was done to compare the mean depth of penetration between the groups. BDM: Biodentine manual, NBDM: Nano BDM, MTA: Mineral trioxide aggregate, MM: ProRootMTA-manual, MU: ProRootMTA-ultrasonic, BDU: Biodentine-ultrasonic, NBDU: Nano BDU

push out bond strength values with standard deviation [Figure 6]. Push out bond strength was higher in Group VI (BDU), and least with Group II (MM). Intergroup comparison revealed a Statistically significant difference among most of the groups ($P < 0.05$) except between Group II versus III, between Group III versus V and between Group I versus II, III, IV, V. Mean push out bond strength values had suggested the bond strength values in the following order:

Group VI (BDU) > Group IV (NBDU) > Group I (NBDM) > Group V (MU) > Group III (BDM) > Group II (MM).

Figure 3: Universal Testing Machine containing cylindrical stainless steel plunger of 1-mm diameter and operating at a speed of 1 mm/min⁻¹ used to apply force on materials, inside root slices.

Figure 4: Mode of failures under stereomicroscope. Inspection of samples under a stereomicroscope at ×10: (a) Cohesive failure showing fracture within the obturating material. (b) Mixed mode of failure with cohesive failure observed within the material at some areas and black arrow indicates the adhesive failures between obturating material and tooth interface.

DISCUSSION

In the present study, the dentin discs of 2 mm thickness were used for the purpose of push out test measurement. Over estimation of the bond strength may occur if thickness of discs is increased due to increase the area of friction.^[7] The chemical and physical properties play a major role in the clinical outcome of root canal filling materials which can be affected by factors such as mixing and placement techniques, delivery system, exposure to various

clinical environments, storage conditions and the ratio of the constituent components.^[8] To fill voids and spaces between the obturant and the tooth structure and to form a fluid tight seal, the root canal filling materials are used with the semisolid or solid core filling material to provide the required adhesion.^[9] In contemporary endodontics the concept of monoblock has increased the potential of creating good adhesion in root canal walls.^[10,11] In the present study all the materials have only one interface that extends circumferentially between the material and the root canal wall which is a primary monoblock.

Hydraulic cements are finely ground materials (powders), yielding complex hydrated products when mixed with water or specific water based component. Any interference in hydration reaction might influence the biological, chemical, and physical properties of the resulting product with altered clinical performance.^[12]

The conventional Proroot MTA and Bio dentine have been modified in present study by the addition of CaCl₂ and Nanoparticulation respectively.

The addition of CaCl₂ at the concentrations of 2%–15% improves physicochemical properties of MTA and shortens the setting time. However, the shortcomings of this modified material include reduced expansion, coherence which might influence the bond strength with radicular dentin. However, considering the advantages of addition of calcium chloride such as shortened setting time and increased biomineralization,^[13] altering the mode of placement

Figure 5: Tubular penetration under confocal laser scanning microscope. Figure 6: Box plot diagram represents distribution of push out bond strength values with standard deviation.

might aid in compensating the reduced bond strength with root canal dentin. Being a viable tool in endodontics, indirect ultrasonic agitation reduces the size of cement particles and consequently increases the total reactive surface by de-clustering the particles that are clogged to each other^[14] resulting in increased flow, setting, and compaction of the material.^[15] In the current study, Ultrasonic activation of CaCl₂ modified MTA resulted in better bond strength even superior to conventional MTA in accordance with the previous study. Besides ultrasonic placement, presence of nanoparticles also has a positive impact on the penetration of material into the dentinal

tubules. There are other factors that might be able to influence the capacity of dentinal tubule penetration of the endodontic filling material: The surface activity of the sealers, the contact angle between sealer and the dentinal walls, the diameter of the opened dentinal tubules and the employed obturation technique.^[16]

Materials with Nano particles have better workability, fluidity and positive influence on hydration process resulting in efficient filling of root canal. In present study, NBD demonstrated increased chemical reactivity is due to higher solubility and surface area as observed by shortened setting time compared to conventional Biodentine. This is substantiated by a fact that a given mass of material in nanoparticle form is much more reactive than the same mass of material made up of larger particles.^[17] It was demonstrated that the more the material is soluble, the higher OH⁻ and Ca²⁺ release which is correlated to the higher solubility recorded for BD. This had led to more Ca²⁺ from nanomaterials.^[18] Setting accelerator effect of the nanoparticles acts as seeds and stimulates the nucleation of calcium silicate, accelerating the hydration process (sowing effect), also helps in accelerating the setting time and hydration process.^[19]

In the present study, the indirect ultrasonic mode of placement had a better bond strength value than

manual with a statistically significant difference. It was observed that Group VI (BDU), has shown highest bond strength values among all other groups. The effective combination of the unaltered hydration which enables the extension of material into the dentinal tubules with indirect ultrasonic activation has resulted in this superior bond strength. However the tubular penetration is lower than that of nanobiodentine with ultrasonic activation which might be due to less particle size of nanobiodentine than Biodentine thus enabling greater penetration. The reduced bond strength of NanoBiodentine compared to Biodentine could be due to the altered density, particle scattering leading to altered hydration characteristics. In the present study, the mean push out bond strength of Group III (BDM) and Group V (MU) had shown similar results with no statistically significant difference, suggestive of ultrasonic activation of MTA could achieve similar results in terms of bond strength even though there is difference in tubular penetration. Except for Groups IV (NBU) and VI (BDU) tubular penetration values are proportionate to push out bond strength values in all the groups of the present study. The greater tubular penetration of Group IV (NBDU) might be due to smaller particle size of nanobiodentine which is further enhanced by indirect ultrasonic activation. However, as previously described it altered the hydration properties resulting in lower bond strength. It was observed that majority of the failures associated with all the groups are of cohesive nature which suggests that the interface between filled material and root dentin was more durable than core material itself. At present the available literature is not sufficient to ensure the long term performance of the bioceramic materials used in the present study. Further research is needed to evaluate the clinical longevity of these modified bioceramic materials.

CONCLUSION

Within the practical limitations of the current *in vitro* study, it can be concluded that indirect ultrasonic activation has resulted in superior interfacial bond strength and tubular penetration than the manual compaction. A combination of Biodentine with indirect ultrasonic activation has resulted in superior bond strength compared to all other groups. On the other hand, manual condensation of MTA has demonstrated the lowest bond strength values. Having greater tubular penetration, Nanobiodentine appears to be a promising root canal filling material.

ABSTRACT

Background and Aim: Although severe acute respiratory syndrome coronavirus 2 primarily affects the respiratory system, involvement of cardiovascular system is not uncommon and a range of cardiac manifestations among Coronavirus Disease (COVID-19) patients were reported in the literature. Furthermore, it is evident from scientific literature that the incidence of deaths and hospitalizations has been increasingly more among COVID-19 subjects with pre-existing cardiovascular disease (CVD). Various pathophysiological mechanisms have been proposed to explain the cardiovascular involvement in COVID-19. Another emerging significant concern is the varying presentations of COVID-19 and side effects due to the medication used in the management of COVID-19 patients. This review attempts to provide a comprehensive overview of the existing literature on the possible association between CVD and COVID-19 with emphasis on the pathophysiological mechanisms, cardiac manifestations, and impact of medications used for COVID-19 on cardiovascular health. Based on the available literature, we conclude that though CVD could not be reckoned as an independent risk factor for COVID-19 infection, it is evident that pre-existing CVD has an influence on the severity of COVID-19 infection and associated mortality.

Relevance for Patients: Literature suggests that people with pre-existing CVD are at increased risk for COVID-19 and associated severity. Consequently, it becomes important to thoroughly gain insights into the possible pathophysiological mechanisms, cardiac manifestations in COVID-19, and the impact of COVID-19 treatment on the cardiovascular system.

1. Introduction

According to the World Health Organization reports, 79.2 million confirmed Coronavirus Disease (COVID-19) cases were detected and nearly 1.75 million deaths were registered across the world as on December 27, 2020 [1]. As there has been a consistent daily increase in the number of COVID-19 confirmed cases in many countries, these numbers may worsen soon and the disease may continue to impose significant burden on the health-care delivery systems worldwide. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus causing COVID-19, primarily affects the respiratory system though the involvement of other organs and systems is not uncommon. The clinical presentations of the disease are too heterogeneous ranging from mild fatigue to severe hypoxia with respiratory failure [2]. This resulted in the categorization of the severity of COVID-19 by Wu and McGoogan [3] and the Society of Pediatrics, Chinese Medical Association [4].

SARS-CoV-2 is an enveloped, single-stranded RNA virus belonging to Coronaviridae. HKU, 229E5, and hCoV-0C43 are among the mild common cold causing coronaviruses affecting human beings. However, SARS-CoV and Middle East respiratory syndrome

coronavirus MERS-CoV are the recently emerged pathogenic coronaviruses, infecting humans, with 8000 and 2500 reported cases worldwide, respectively [5,6]. The major route of transmission of SARS-CoV-2 is through respiratory droplets. The secondary attack rate for COVID-19 ranged from 0.5 to 5% [7,8]. Incubation periods for the disease did not differ significantly between people with the 95% confidence interval of the median incubation period for SARS-CoV-2 being 4.5–5.8 days and a vast majority of the affected demonstrating symptoms within 12 days from the time of exposure [9]. Shi *et al.* reported that <20% of COVID-19 affected subjects had significant symptoms such as dyspnea, tachypnea, and hypoxemia. Symptoms of critical COVID-19 infections include respiratory failure, multi-organ failure, and sepsis induced hypotension [10]. Development of cardiovascular disorders was reported in some COVID-19 cases and the literature suggests that people with pre-existing cardiovascular disease (CVD) are at increased risk for COVID-19 and associated severity [11]. With this background, the objective of this review is to provide a comprehensive overview of the association between COVID-19 and CVD.

2. CVD and Coronavirus: an epidemiological perspective

CVD has been identified as a common comorbidity among patients infected with viruses belonging to the Coronavirus family. The prevalence of CVD among SARS patients was 8% and is reported to be a significant contributor for the increased risk of death among those affected with SARS [12,13]. With regard to MERS, hypertension and CVD were prevalent among nearly 50% and 30% of the affected subjects, respectively [14]. This association is apparently evident in the context of COVID-19 as well with presence of cardiovascular comorbidities among the COVID-19 affected at an increased frequency. It was hypertension as a comorbidity and 17% of COVID-19 confirmed cases had coronary heart disease [15]. Yang *et al.* conducted a meta-analysis to document the prevalence of comorbidities among COVID-19 patients and found that hypertension, diabetes mellitus, and CVD are among the common comorbidities among the infected patients. It was reported that the 95% confidence interval for the prevalence of CVD was 4–7% [16]. The presence of underlying cardiovascular comorbidities was also found to be associated with increased mortality among COVID-19 infected. In a study conducted by Wang *et al.* in Wuhan, China, 31% of the COVID-19 cases had hypertension and this percentage increased to 58% when patients admitted in ICU were exclusively considered [17]. Similarly, the prevalence of hypertension and coronary heart disease was 30% and 8% in another study conducted by Zhou *et al.* in China [18]. Although the exact mechanism leading to these observations is not known, the interference of age as a confounding factor in the association between CVD and COVID-19 cannot be ignored, with older people demonstrating high prevalence of CVD and increased susceptibility of a symptomatic COVID-19 infection due to a relatively weaker immune system among the elderly.

3. Pathophysiological mechanisms

The elevated expression of several cardiovascular biomarkers has been reported in severe COVID-19 cases [17-19]. These changes support involvement of the cardiovascular system, which can be explained by the combined effects of several mechanisms.

3.1. Renin-angiotensin system (RAS) imbalance

Angiotensinogen is converted to angiotensin I (Ang-I) by the protease rennin, which consequently gets converted by Angiotensin Converting Enzyme (ACE) to angiotensin II (Ang-II). ACE2 facilitates the conversion of Ang-II to angiotensin-(1–7), by removal of carboxy-terminal phenylalanine, which on binding with the MAS receptor results in vasodilation and anti-inflammation. However, it is scientifically established that to facilitate the fusion with host cells, SARS-CoV binds to human ACE 2 with the amino terminal of its spike protein [4]. SARS-CoV2 being a coronavirus that belongs to the β genus may also have ACE2 as its binding receptor. The expression of ACE2 on cells is downregulated in SARS-CoV infection leading to disruption in the physiological balance between ACE/ACE2 and Ang-II/angiotensin-(1–7). This marked downregulation of ACE2 and the corresponding upregulation of Ang-II may aggravate perpetuate cardiac injuries [20]. High Ang II levels in plasma among COVID-19 patients adds strength to the supposition that SARS-CoV2 binds to ACE2 resulting in the elevated production of Ang II through RAS. This increases burden on the cardiovascular system as the heart load increases leading to cardiomyocyte hypertrophy and hypertension [21].

3.2. Overactivation of the immune system

Replication of virus following the host cell fusion and this invasion of alveolar surfaces would result in alveolitis and the invasion of the cardiac muscle cells results in edema and lysis of the cardiomyocytes, which further lead to release of pro-inflammatory cytokines [22]. The deposition of pro-inflammatory cytokines and the filtration of inflammatory cells at the site of injury causes “inflammatory storms” which warrants an overactivation of the immune system. This leads to damage of cardiomyocytes and decreases the adherence of the atherosclerotic plaques in coronary vessels. All these mechanisms predispose to cardiovascular events [22]. Huang *et al.* reported the cytokine profiles of COVID-19 infected subjects with elevated Interleukin (IL)-2, IL-7, interferon- γ , and tumor necrosis factor α [11]. Virus associated was reported to be associated with increased COVID-19 fatality in a multicentric study among infected subjects in Wuhan, China, where significant differences in ferritin levels and IL-6 were between survivors and non-survivors [19]. In autopsy findings, cytokine storm induced by the inflammatory response syndrome to COVID-19 was discussed to have resulted in cardiac interstitial mononuclear inflammatory infiltrates [23,24].

3.3. Decreased partial pressure of oxygen in blood

Damage to alveolar cells in COVID-19 patients results in hypoxemia. As the partial pressure and saturation of oxygen falls

consistently there is deposition of oxygen free radicals, which on circulation across the body damages the cardiomyocytes. Another mechanism is the activation of NADPH oxidase enzymatic complex by the downregulation of ACE2 and corresponding upregulation of Ang-II in COVID-19. Ang-II binds to Angiotensin Type I Receptor (AT1R) which stimulates the activity of NADPH oxidase that reduces oxygen to superoxide. While clear underlying mechanisms for stimulation of NADPH oxidase are complex, it is known to occur at the genetic, transcriptional, and post-transcriptional levels involving multitude of signaling molecules and scaffolding proteins [25]. ACE2 deficiency was shown to increase NADPH oxidase activity and resulted in oxidative stress in the study conducted by Wysocki *et al.* [26]. To accommodate for the metabolic demands, blood flow intensifies increasing the individual's risk for heart failure. Furthermore, hypoxemia is an independent predecessor for inflammatory response that promotes "inflammatory storm" and contribute toward incidence of cardiovascular events [27].

3.4. Elevated catecholamine levels in plasma

An initial response to viral invasion is the activation of immune system, and the interaction between viral and host cells is a complex phenomenon. Besides, stimulation of α 1-adrenoceptors by catecholamines can reinforce the vasoconstriction caused by excess Ang-II as a result of downregulation of ACE2 and could contribute toward a significant increase in vascular resistance. Moreover, catecholamines stimulate β 1-adrenoceptors in the kidney to increase renin secretion that consequently increases Ang-II resulting in further deterioration of cardiovascular health. Response from the emotional perspective such as anxiety, fear also lead to increased production of catecholamines the concentration in plasma of which is directly related to hypertension, coronary artery disease, and cardiac failure. Increased level of catecholamine levels in plasma also has the implication of myocardial toxicity that could result in circulatory disturbances and arrhythmias [26]. Although a direct study of catecholamines among COVID-19 subjects could offer useful insights, the scope for these observations is hampered by severe illness such as respiratory failure, compromised cardiovascular health, and shock and more so among those on adrenaline infusion.

4. Cardiovascular manifestations in COVID-19

Although it is known that SARS-CoV 2 primarily affects the respiratory system, the negative impact COVID-19 has on cardiovascular health cannot be overstated. It has been thoroughly established in literature that cardiac manifestations contribute significantly towards COVID-19 case fatality rates [27-29]. The following are the most common cardiac manifestations observed among COVID-19 patients.

4.1. Myocardial injury

Regardless of the presence or absence of respiratory symptoms, it has been observed that ischemic and non-ischemic myocardial injury is one of the significant outcomes of COVID-19

infection [30,31]. The incidence of myocardial injury as a COVID-19 manifestation varied between 7% and 28% among hospitalized COVID-19 patients in the scientific literature [32]. High spikes in troponin levels were identified in patients with severe disease. In a cohort study conducted by Shi *et al.*, nearly 20% of the hospitalized patients demonstrated cardiac injury. This finding gains significance in light of the fact that COVID-19 fatality rate is 10 times higher among patients with cardiac injury compared to those who do not have myocardial injury [33]. Zhou *et al.* reported in their multicentric study that the proportion of myocardial injury among COVID-19 non-survivors was 46% as compared to 1% among survivors [18].

4.2. Heart failure

Among COVID-19 patients with previous history of cardiovascular problems and undiagnosed heart diseases, heart failure may occur [34]. It is imperative to focus on the findings reported by Zhou *et al.*, where the proportion of heart failure was 52% among non-survivors as compared to 12% among survivors [18]. These findings corroborated with those reported by Chen *et al.*, where heart failure was noticed among 49% and 3% of the non-survivors and survivors, respectively [35]. It is also reported in the literature that COVID-19 patients with the previous heart failure could possibly experience an acute decompensation [36].

4.3. Cardiac arrhythmias

Arrhythmias are another common manifestation among COVID-19 patients. While progressive arrhythmias among infected individuals could be reckoned as an indication for cardiac involvement, it is not uncommon for arrhythmias to be the initial presentation of COVID-19. It was postulated by Guo *et al.* that high TnT levels have an increased incidence of malignant arrhythmias [37]. Palpitations were reported to be among the most common clinical presentations of COVID-19 in a study conducted by Liu *et al.* in Wuhan, China [38]. Although the reasons for palpitations and the nature of arrhythmias were not mentioned by Wang *et al.*, they reported increased frequency of arrhythmias among COVID-19 patients in ICUs compared to those who did not require intensive care [17].

4.4. Thromboembolism

It has been thoroughly established in the literature that COVID-19 activates the coagulation cascade. In a study conducted by Han *et al.*, a significant reduction in circulating antithrombin III, substantial increases in the fibrinogen and D-dimer levels were reported among COVID-19 patients as compared to healthy controls. Severe inflammation in COVID-19 is also marked by higher platelet counts compared to non-COVID-19 patients with pneumonia [39]. Tang *et al.* reported higher incidence of disseminated intravascular coagulation (DIC) among the deceased compared to the survivors, and a short duration of 1–12 days was identified between the time of hospitalization and the onset of DIC [40]. Literature suggests that almost a quarter of COVID-19 patients had deep venous thrombosis [41]. The rationale for

this observation could be elevated levels of D-dimer, fibrinogen among COVID-19 affected [39]. An association between severity of COVID-19 and the levels of these coagulation markers was also reported by Xiong *et al.* in a meta-analysis [42]. Any level of D-dimer more than 1µg/ml was reported to be a contributing factor for in-hospital deaths by Zhou *et al.* [18]. The incidence of venous thromboembolism as a COVID-19 manifestation varied between 20% and 43% among COVID-19 patients requiring intensive care in spite of preventive anticoagulation. To prevent incident thrombophlebitis among COVID-19 patients, heparin is recommended by the WHO, due to its pleiotropic properties, for hospitalized COVID-19 patients [43]. Yin *et al.* reported improved prognosis with heparin use among hospitalized COVID-19 patients with elevated D-dimer levels [44].

5. Cardiac consequences of COVID-19 treatment

Varying presentations of COVID-19 and side effects due to the medication used in the management of COVID-19 patients emerged as a significant challenge for physicians providing services for these patients. Among various pharmacological management strategies of COVID-19, the use of antiviral drugs, anti-malarial drugs, immunomodulatory medicines, glucocorticoids, and plasma from COVID-19 recovered patients is the common [45-47]. Chloroquine and hydroxychloroquine result in alkalization of the intracellular phagolysosome. This leads to under-glycosylation of ACE2 receptors thus limiting the fusion of SARS-CoV 2 and the host cells [45]. Regardless of the concomitant use of COVID-19, hydroxychloroquine was found to be decreasing the viral carriage among the in-hospital COVID-19 affected [48]. However, these drugs prolong the QT interval and may result in fatal arrhythmias, especially in cases with electrolyte abnormalities [49]. Furthermore, thorough monitoring for hypotension and bradycardia is warranted among COVID-19 patients using chloroquine as the drug holds the potential for inhibiting CYP2D6 resulting in elevated levels of beta blockers [50]. The antiviral drugs used in the management of COVID-19 patients may result in bradycardia, prolongation of QT and PR interval [49,51,52] and may have an influence on the warfarin dosing [53]. This possibility of drug-drug interaction between antiviral medication and the anticoagulants is an area of concern. The side effects of remdesivir, which is established to be contributory toward faster recovery from COVID-19 infection [54], are increase in liver enzymes and respiratory failure [55]. Monitoring ECG parameters is extremely important in the context of COVID-19 pandemic in light of the fact that the medications used in the management of this disease and also the possible hypokalemia subsequent to diarrhea, which is one of the clinical features in COVID-19 affected, may prolong the QT interval increasing the risk for torsade Despointes.

Although there is uncertainty whether RAAS inhibition have any effect on the ACE2 expression [56,57], use of RAAS inhibitors emerged as an area of concern as ACE2 protein is used by SARS-CoV2 for cellular entry [58]. However, the general recommendation amidst uncertainty is to continue the use of

RAAS inhibitors among stable COVID-19 patients [59]. The negative impact of cytokine release syndrome, among COVID-19 affected, on the cardiopulmonary system prompted the use of corticosteroids to curtail the overactivation of the immune system [60]. Nevertheless, use of corticosteroids is routinely avoided to decrease the risk of exacerbation of the prevailing lung damage [61]. Therefore, it has been recommended that screening of COVID-19 patients for ESR, platelet count, serum ferritin levels and obtaining a hemophagocytic response (H Score) be done in the identification of COVID-19 patients where immunosuppression could be necessary.

6. Conclusion

The notion of increased risk of COVID-19 infection among subjects with pre-existing CVD remains equivocal as the numbers suggest a comparable prevalence of CVD among COVID-19 infected and the general source population. Nevertheless, CVD apparently is associated with increased hospitalizations and death among COVID-19 cases. It is evident that pre-existing CVD may aggravate the COVID-19 disease course with the presentation of aforementioned cardiac manifestations. Moreover, the pathophysiological mechanisms involved in COVID-19 may lead to cardiomyocyte hypertrophy and damage, circulatory disturbances, and arrhythmias. Therefore, close monitoring of COVID-19 subjects for cardiovascular health is warranted and it is advisable for subjects with pre-existing CVD to be more careful in practicing the precautionary measures such as maintaining social distancing, avoiding unnecessary travel, following respiratory hygiene/cough etiquette to avoid COVID-19 infection.

Abstract:

Background: Periodontal disease is an inflammatory process resulting in clinical attachment loss (CAL), pocket depth (PD), and resulting in the loss of alveolar bone. Diagnostic imaging provides an adjunctive guidelines to assess the alveolar bone height in addition to clinical parameters such as PD and CAL. **Aims and Objectives:** The objectives of the study are to determine whether the digital intraoral periapical (IOPA) radiographs can be reliably used as an alternative to cone-beam computed tomography (CBCT) in the diagnosis of intrabony defects. **Materials and Methods:** A total of 25 patients with the presence of intrabony defects were included in the study. All the radiographic parameters were recorded using digital IOPA and CBCT. Various intrabony defect morphological characteristics such as height, depth, width, and angle were measured and compared between digital IOPA and CBCT. **Statistics:** The data was subjected to statistical analysis. Mann-Whitney *U*-test was performed for interexaminer comparison and independent *t*-test for intergroup comparison. **Results:** The mean intergroup comparison values between digital IOPA and CBCT in relation to defect width were 3.22 ± 1.10 and 3.20 ± 1.16 , respectively ($P = 0.970$), in relation to defect depth were 7.71 ± 2.3 and 7.91 ± 2.4 , respectively ($P = 0.769$), in relation to defect height were 3.80 ± 1.20 and 3.90 ± 1.2 , respectively ($P = 0.794$), and in relation to defect angle were 34.82 ± 8.4 and $35.28 \pm 0.8.6$, respectively ($P = 0.851$). **Conclusion:** With the drawbacks of such as high radiation exposure, unavailability, and high financial cost, digital IOPA with digital software can be used as an alternative to CBCT for measuring intrabony defect morphological characteristics in periodontitis patients.

INTRODUCTION

Periodontal disease is an inflammatory process resulting in clinical attachment loss (CAL), pocket depth (PD), and resulting in the loss of alveolar bone. One of the characteristic symptoms of destructive periodontal disease is the alveolar bone loss and this bone destruction pattern is divided into horizontal (even) and oblique (vertical/angular) bone defects. The bone destruction in vertical patterns does not proceed in a symmetrical pattern. The magnitude of bone destruction varies in different sites around the tooth, which explains why the crest of the alveolus does not correspond to the cemento-enamel junction (CEJ), and it is not parallel to it. Hence for the diagnosis, treatment planning, and prognosis of intrabony defects evaluation of the defect morphology is crucial.^[1]

Diagnostic imaging provides an adjunctive guidelines to assess the alveolar bone height as well as the occurrence of intrabony defects in addition to clinical parameters such as PD and CAL.^[2] The precise methods for analyzing the morphological

characteristics of the intrabony defects were clinical observation and topography.^[3]

In the diagnosis of periodontal diseases, radiographs play a crucial role by depicting the nature and amount of injury that occurred to the alveolar tissues. For the diagnosis of the amount of alveolar bone loss and intrabony defect morphology, various intraoral and extraoral oral imaging modalities were available.^[3]

How to cite this article: Adurty C, Tejaswi KS, Shivani CR, Navya D, Gopinath C, Dhulipalla R. Accuracy of digital intraoral periapical radiography and cone-beam computed tomography in the measurement of intrabony defects: A comparative study. *J Indian Soc Periodontol* 2021;25:491-5.

Among the two dimensional (2D) intraoral imaging modalities, digital intraoral periapical (IOPA) radiographs and bitewing radiographs can be cheap, easily acquired, and provide high resolution images.^[4,5] However despite of these advantages, 2 Dimensional imaging modalities are having limitations such as overlapping of anatomical structure and difficulties in standardization.^[6-8]

To overcome the disadvantages of 2D imaging, cone-beam computed tomography (CBCT) (3D imaging) provides 3D analysis and rapid volumetric image in the field of diagnostic imaging, which include the elimination of distortions and the ability to visualize structures in all three orthogonal planes.^[9-11]

According to the literature, the use of digital IOPA had showed better results close to intrasurgical analysis, whereas 3D imaging showed an 80%–100% sensitivity in the detection of intrabony defects.^[12]

Hence, the purpose of the study is to determine whether the digital periapical radiographs can be reliably used as an alternative to CBCT in the diagnosis of intrabony defects.

MATERIALS AND METHODS

The present study was conducted on 25 subjects, selected from the Department of Periodontology and Implantology, Teaching Institution. The Study Protocol was approved by the Institutional Ethical Committee. After explaining the procedure, written and informed consent was obtained from patients who are willing to participate in the study. A total of 25 patients diagnosed with chronic and aggressive periodontitis with the presence of intrabony defects were included in the study. All the radiographic parameters were recorded using digital IOPA and CBCT.

Study design

The patients were selected according to the following criteria:

Inclusion criteria

1. Patients should be in between 18 and 56 years of age
2. Patients diagnosed with chronic and aggressive periodontitis (localized/generalized)
3. Transgingival probing PD \geq 6 mm and CAL \geq 7 mm.

Exclusion criteria

1. Patients who were systemically compromised
2. Pregnant and lactating females
3. Patients who received periodontal treatment in the past 6 months.

Clinical examination was performed by postgraduates under the supervision of senior periodontist. Clinical attachment level (CAL) and trans gingival probing depth were taken.

IOPA was performed using the Scanora digital software (2.2) using the long-cone paralleling technique with a bite registration positioning device. The exposure setting was 70 kVp with 12–25 mA. The millimetric grid used for digital intraoral radiographs was composed of 1-mm copper squares. These squares were used to calibrate the measurement tool of the viewing software to compensate for the elongation and foreshortening of the image.

A CBCT imaging technique was performed on each patient (9300 CBCT, carestream dental). The exposure settings were 80 kV and 10 mA. The scanning parameters selected were 90 μ m voxel size, 12 s acquisition time, and 5 cm \times 5 cm field of view. The CS imaging software module (version 2.2, CS 9300, Carestream Health, Inc, 150 verona street, Rochester street, NY, USA, 14608) was used to reconstruct and reformat the volume and resulting slices and complete all measurements. The axial slices in CBCT were used to verify the presence of combined bony defects, according to the classification of Goldman and Cohen.

Radiological parameters

1. The height of the defect: Distance from the CEJ to the alveolar crest (AC)
2. Depth of the defect: Distance from CEJ to the base of the defect
3. Width of the defect: Highest point of the AC to the root adjacent to the defect
4. Defect angle: Two lines that represent the root surface of the involved tooth and the bone defect surface.^[13]

Imaging evaluation

The images were analyzed by two examiners: a radiologist with 2 years of experience and examiner 2 was a third-year postgraduate student in periodontology.

Radiographic assessment was done by using Image Assistant software for periapical radiographs and CBCT according to Misch *et al.* At each site, three measurements were taken, they are as follows: (1) the height of the AC, measured from the CEJ to the AC, (2) the depth of the defect, measured from the CEJ to the bottom of the defect (BD), and (3) the width of the defect, measured from the highest point of the AC to the dental root adjacent to the defect. If restorations were present, the apical margin of the restoration replaced the CEJ as a fixed reference point. Defect angle was measured from the line drawing from the CEJ to the BD, and the other line extends from the BD to the lateral margin of the defect [Figures 1a-d and 2a-d].^[7]

Interexaminer agreement was evaluated as the standard error of the mean difference of the measurements performed by each of the two examiners. These were <1 . Ninety percent of the first examiner measurements were within the range of $\pm 3^\circ$ relative to the values obtained by the second examiner. Images were interpreted by an experienced orofacial radiologist.

Statistical analysis

The data was subjected to statistical analysis. Mann–Whitney *U*-test was done for interexaminer comparison and independent *t*-test for intergroup comparison. $P < 0.05$ was considered as statistically significant.

RESULTS

The mean interexaminer comparison values for CBCT in relation to defect width between the two examiners were 25.40 and 25.60, respectively ($P = 0.961$). The mean interexaminer comparison values for CBCT in relation to defect depth between the two examiners were 25.58 and 25.42, respectively ($P = 0.969$). The mean interexaminer comparison values for CBCT in relation to defect height between the two examiners were 25.74 and 25.26, respectively ($P = 0.907$). The

mean interexaminer comparison values for CBCT in relation to defect angle between the two examiners were 25.46 and 25.54, respectively ($P = 0.984$) [Table 1].

The mean interexaminer comparison values for digital IOPA in relation to defect width between the two examiners were 25.54 and 25.46, respectively ($P = 0.984$). The mean interexaminer comparison values for digital IOPA in relation to defect depth between the two examiners were 25.52 and 25.48, respectively ($P = 0.992$). The mean interexaminer comparison values for digital IOPA in relation to defect height between the two examiners were 25.32 and 25.68, respectively ($P = 0.930$). The mean interexaminer comparison values for digital IOPA in relation to defect angle between the two examiners were 25.52 and 25.48, respectively ($P = 0.992$) [Table 2].

The mean intergroup comparison values between digital IOPA and CBCT in relation to defect width were 3.22 ± 1.10 and 3.20 ± 1.16 , respectively ($P = 0.970$). The mean intergroup comparison values between digital IOPA and CBCT in relation to defect depth were 7.71 ± 2.3 and 7.91 ± 2.4 , respectively ($P = 0.769$). The mean intergroup comparison values between digital IOPA and CBCT in relation to defect height were 3.80 ± 1.20 and 3.90 ± 1.2 respectively ($P = 0.794$). The mean intergroup comparison values between digital IOPA and CBCT in relation to defect angle were 34.82 ± 8.4 and $35.28 \pm 0.8.6$, respectively ($P = 0.851$) [Table 3].

DISCUSSION

To our knowledge, this was the first study to compare the intrabony morphological parameters between CBCT and digital IOPA techniques. The mean age of the patients included in this study was 35 years and there was an equal distribution of genders between the two groups.

The normal bone height in relation to CEJ ranges from 1 mm to 3 mm in patients without periodontal disease. The mean alveolar bone height in relation to CEJ For adults with mean age

of 35 years was 1.4mm and it was in accordance with previous literature. Therefore, the mean alveolar bone height above 1.4 mm from the CEJ was considered as the level for the presence of periodontal disease.^[14]

The results of the Mann-Whitney U-test for comparison between the measurements made by the two examiners showed $P < 0.05$ for all the measurements indicating that the scores were nonvariant for data collected by the examiners. The results demonstrate a high agreement between the two examiners, revealing good calibration and reliability of the results of the study.

In detection of the bone loss patterns, no statistical difference was seen between the two groups. Buccal and palatal/lingual surface measurements in axial section measurements were not compared due to consideration with limitations of periapical images. The agreement of the absolute measurement evaluation was made between the two examiners, $P < 0.05$ depicts that for

the assessment of bone loss in both buccal and lingual/palatal surfaces, reliably cross-sectional slices can be used. An agreement in identifying vertical bone loss in 95% of the cases was present between the two examiners.

The results demonstrate a similar accuracy of periodontal bone level measurements when compared to Vasconcelos study.^[13]

The delineation of lamina dura, bone quality, and contrast rating remains better for the digital intraoral images, which contain a higher resolution compared with CBCT.^[12] The present study shows that there were no statistically significant differences observed in assessing bone level measurements in CBCT and digital intraoral radiographic techniques which were similar to the study conducted by Vandenberghe *et al.*^[12]

With respect to width and depth of the defect, no statistically significant difference was observed, which is similar to Misch *et al.*'s study.^[7] In contradiction to the present study, Mol and Balasundaram conducted a study on human skulls where they demonstrated that CBCT was slightly more accurate than intraoral radiographic techniques.^[6]

Various authors had emphasized the importance of defect angle in the establishment of prognosis and calculating the amount of

bone fill after intrabony defect treatment. For the determination of CAL gain in intrabony defects, radiographic defect angle can be used as a presurgical parameter when Guided Tissue Regeneration (GTR) was used for the treatment according to Cortellini and Tonetti.^[15] Small defect angles (0–45) have greater defect fill potential in periodontal surgery when compared to wide angles (45–90) in the analysis done before the treatment phase.^[16,17] In the present study, the mean radiographic defect angles compared between CBCT and Digital IOPA were 35.28 ± 8.64 and 34.80 ± 8.4 , respectively. No statistically significant difference between the two groups in preoperative assessment of defect angle was observed.

In this study, we found that the measurements of height, depth, and defect angle of vertical bone defect obtained by the two techniques were very close, and the difference in the measurements was not significant. The studies used defect angle at baseline with end treatment results in periodontal surgery by enamel matrix derivative and by using a DIA tool.^[18,19]

The limitations of the present study were small sample size and less duration of the study. As with CBCT, the presence of metallic restorations and high resolution is required for the study of intrabony defect morphological characteristics in periodontal diseases.

CONCLUSION

Radiographic defect angle plays a prominent role in assessing the prognosis of the intrabony defects in periodontal disease. Hence, presurgical measurement of these parameters is important and with the drawbacks of such as high radiation exposure, unavailability, and high financial cost, digital IOPA with digital software can be used as an alternative to CBCT for measuring intrabony defect morphological characteristics in periodontitis patients.

ABSTRACT

The primary etiologic factor for periodontal diseases is “Dental plaque.” Although pathogenic bacteria in dental plaque are required for the incidence of periodontal disease, a susceptible host is also very important. The susceptibility of the host can be modified by many systemic factors with hormones level being one. The periodontium shows an exaggerated inflammatory response to plaque modified by female sex hormones during puberty, pregnancy, in women taking oral contraceptives, and at the postmenopausal stage. This review provides an in detail analysis of how periodontium is influenced by the fluctuation in sex steroid hormones of females during different phases of their lifetime and to discuss how much the same hormone at different ages and stages shows an exaggerated gingival response to plaque.

KEYWORDS: *Female sex hormones, menopause, periodontium, pregnancy, puberty*

INTRODUCTION

The periodontium, defined as the tissues that surround and support the teeth, includes the gingivae, bone, cementum, and periodontal ligament. Periodontitis is the result of an inflammatory response by the host to a bacterial infection of periodontal tissues. Numerous species of pathogenic bacteria present in subgingival plaque can interrupt the routine homeostatic processes, attack the surfaces of the tooth, infiltrate periodontal tissues, and organize themselves in the form of biofilm.^[1] The host’s immune response, triggered by microorganisms and their metabolites, stimulates the synthesis and release of cytokines, inflammation mediators, and metalloproteinases of the matrix, leading to the damage of the tissues.^[2] The disease progression and severity depend on the aggressiveness of the subgingival biofilm which is countered by the host’s immune response^[3,4] and further modulated by the genetic and epigenetic context and also environmental factors such as gender, age, smoking, and oral hygiene.^[5,6] It is clearer that, due to bacteremia and the systemic release of endotoxins, the presence of pathogenic bacteria in periodontal lesions is connected to various systemic disorders, including cancer, diabetes mellitus, rheumatoid arthritis, cardiovascular disease, infertility, and adverse birth outcomes.^[7] Female periodontium

undergoes developmental changes beginning at puberty and progressing through menstruation, pregnancy, and menopause depending on the levels of sex hormones in the body.

SEX HORMONES AND PERIODONTAL CHANGES

Ovaries secreting estrogen is responsible for the maintenance of secondary sex characteristic and uterine growth while progesterone influences the second half of the menstrual cycle and pregnancy. Progesterone influences the vascularity of the gingival and periodontal tissues through the receptors present in them.^[8,9]

This leads to the production of prostaglandins and the movement of polymorphonuclear leukocytes further leading to increases inflammation while estrogen increases the inflammatory component of gingiva without deposition of bacterial plaque.^[9]

Raised hormonal content is act as a feeder and growth factor for black-pigmented bacteria including

Bacteroides, *Prevotella* *intermedia*, and the *Capnocytophaga* species. Studies supporting this hypothesis have shown that preeclamptic women are infected in higher proportion as compared to nonpreeclamptic or normal pregnant women.^[10]

Hormonal fluctuations during a female's lifetime may produce an exaggerated inflammatory response to dental plaque, resulting in gingivitis. Dental plaque deposition and high inflammatory gingiva (bleeding and redness) are typical features of hormone-associated gingivitis. Symptoms vary according to individuals' responses to hormonal changes. Susceptibility to infections (e.g., periodontal infection) increases due to variations in the immune system and can be elucidated by the hormonal changes and suppression of T-cell activity, decreased neutrophil chemotaxis and phagocytosis, altered lymphocyte response and depressed antibody production, chronic maternal stress, and even nutritional deficiency concomitant with increased nutritional demand by both the mother and the fetus. The amount of dental plaque and inflammation is not dose dependent; thus, even in a small quantity of irritants can induce heightened response depending on the individuals' immune reaction.

Hormone-associated gingivitis is reversible following puberty or pregnancy, and no radiographic bone loss is observed.^[11] The incidence of periodontitis can be as high as 23% in adult women, but half of the women with periodontitis above the age group of 55 years still have healthy teeth.^[12]

As a woman's health changes throughout her lifetime from prepuberty to puberty to postmenopausal, the body undergoes continuous changes in hormonal levels throughout the life cycle, thus leading to change in the body environment with specific oral health implications. Furthermore, menopausal and postmenopausal women have low levels of sex hormone levels, which also have some oral health problems associated with gingival.^[13]

PUBERTY

Puberty is associated with increased levels of progesterone and estrogen levels. These hormones act as a growth factor for the periodontis causing bacteria to grow and dwell in this specific age group; thus, periodontis is more common in the pubertal age group as compared to children in their prepubertal stage. Gingivitis associated with hormonal presence is highly sensitive to their presence and they return to normal condition in the circumpubertal stage. Most females with healthy gingivae likely will not develop significant periodontal changes. A higher population of bacteria in subgingival pockets is present during puberty, which may selectively accumulate estradiol and

progesterone.^[9] Meticulous oral home care consisting of regular brushing and flossing and routine dental visits may help prevent the development of gingivitis.

MENSTRUATION

Many women report an increase in gingival inflammation and discomfort associated with their menstrual cycle. "Gingival inflammation was lower during menstruation than during ovulation and premenstruation. "This may be attributed to the hormone known as serum estradiol, which is a natural form of estrogen that peaks and drops during ovulation and premenstruation. During the luteal phase of the menstrual cycle, levels of progesterone peak leading to elevated inflammatory changes in gingiva and periodontium. It is at its peak at the beginning of the cycle which eventually subsides with time. This can be hypothesized due to changes in bacterial flora.^[14]

PREGNANCY

Maternal periodontal disease strongly influences pregnancy outcome is a well-known fact.^[15] Researchers consider that hematogenous transport of bacteria and/or pro-inflammatory mediators from sites of periodontal infection into the placenta, fetal membranes, and amniotic cavity induces pathological processes that lead to these adverse outcomes. An exaggerated gingival inflammatory response to dental plaque is the primary cause of gingivitis, which usually starts around the 2nd month of pregnancy and generally resolves following parturition. In addition, pregnancy may accelerate the development of periodontitis (deep pockets and bone loss around teeth).^[16] There may also be a link between periodontitis and adverse pregnancy outcomes, including preterm delivery and low birth weight babies.^[17]

Periodontal treatment of the pregnant patient has been controversial. Findings from one clinical study reported that periodontal treatment during the second and third trimesters of pregnancy is safe, but the risk of adverse effects, such as preterm delivery (birth occurring before 37 weeks of pregnancy), low birth weight, fetal growth restriction, or preeclampsia, is not reduced.^[18,19] On the other hand, data from four clinical trials found that periodontal treatment in pregnant women may lower the incidence of preterm delivery and low birth weight babies. Maternal and fetal exposures to Gram-negative periodontal bacteria may trigger inflammatory events in both the mother and the fetus, which may stimulate the early rupture of membranes and parturition.^[20]

USE OF ORAL CONTRACEPTIVES

Oral contraceptives enhance periodontal break down reducing the resistance to dental plaque and can

induce gingival enlargement in otherwise healthy females.^[21] The long-term use of oral contraceptives may cause clinical attachment loss, increased gingival inflammation, and gingival enlargement. Therefore, it is expected that the same gingival changes seen during pregnancy will also be seen in women taking oral contraceptives. Women using contraceptives have poor periodontal and gingival health. Currently, there are newer oral contraceptive formulations in the market which contain a lower concentration of hormones, resulting in a milder inflammatory response of the gingival to dental plaque.^[22]

MENOPAUSE

Menopause is associated with important systemic and oral changes. The sudden decrease in estrogen levels that happens in menopause is considered to be the main cause of primary osteoporosis, which also affects jawbones. It has been suggested that this reduction in bone mineral density could contribute to the progression of periodontal disease. Besides their effect on bone, estrogens also interfere with other periodontal tissues (gingiva and periodontal ligament) and influence host immune-inflammatory responses. Change in salivary viscosity, especially in postmenopausal women, also leads to a change in the microbial environment of the periodontium.

The relationship between menopause and periodontal disease is difficult to establish due to the multitude of factors involved. If any relationship is found, it will always be less significant comparing to other well-known risk factors of periodontal disease.^[23]

Bisphosphonate-associated osteonecrosis of the jaws is characterized by pain or swelling in the affected jaw, an irregular mucosal ulceration with exposed bone in the mandible or maxilla, and infection. The pharmacist and dentist need to be aware that the patient will be or currently is taking a bisphosphonate. Commonly prescribed bisphosphonates include zoledronic acid (Zometa), pamidronate (Aredia), alendronate (Fosamax), ibandronate (Boniva), risedronate (Actonel), tiludronate (Skelid), clodronate (Bonafos), and etidronate (Didronel).^[24,25]

Additional oral symptoms experienced by postmenopausal women include burning oral sensations – especially on the tongue – altered taste sensations, and a decrease in salivary flow. If xerostomia is present, dental plaque may accumulate secondary to reduced salivary function/flow, leading to caries and, possibly, gingivitis.^[26]

CONCLUSION

Female sex hormone influences the bacterial flora further leading to onset and progression of the gingivitis and periodontal disease during puberty, menstruation, and pregnancy.

ABSTRACT

Aim: The aim of this study was to compare the cleaning efficacy of three different rotary instrumentation systems in root canal preparation of primary anterior teeth.

Materials and Methods: Thirty primary anterior teeth were freshly extracted and divided into three groups of ten teeth each. In Group I, root canals were instrumented with ProTaper, Group II with K3, and Group III with Hero 642 rotary file systems. After canal preparation, the teeth were sectioned longitudinally and visualized under standard error of the mean at coronal, middle, and apical thirds. Debris and smear layer removal efficacy was evaluated, and the data obtained were subjected to Kruskal–Wallis ANOVA test and Mann–Whitney *U*-test.

Results: Statistically significant difference was noted in debris and smear layer scores at apical thirds ($P < 0.05$) between three groups with the highest efficacy for ProTaper followed by K3 and Hero 642 rotary systems. At coronal and middle thirds, K3 performed better than ProTaper file system.

Conclusion: All the three groups showed decreased smear layer removal at the apical third. However, ProTaper and K3 rotary files showed significantly better cleaning efficacy at the apical third when compared to Hero 642 rotary files.

Keywords: Debris removal, Hero 642, K3 files, ProTaper rotary files, smear layer

INTRODUCTION

Pediatric endodontics is a branch of dentistry that deals with the management of pulpal pathology in children. Early loss of primary teeth leads to loss of space, so as to maintain the tooth in its normal physiological function in the dental arch till its normal exfoliation pulpal procedures like pulpectomy are carried out in the teeth with infected pulp tissue.^[1]

Till date, root canal preparation has been made with a variety of instruments and techniques. In 1962, Nickel–titanium (NiTi) alloys were first developed, and in 1988, Walia announced that root canal files were made of this NiTi alloy which consists of 55% (w/w) nickel and 45% (w/w) titanium.

NiTi files have 2–3 times higher elastic flexibility in bending and torsion as well as superior resistance to corrosion when compared with stainless steel files. In the present era, several rotary NiTi endodontic systems have been familiarized in the market. The rotary system should be of the right choice as the individual designs and features affect the performance of the rotary instruments.^[2]

Smear layer is formed on the walls of the canal during biomechanical preparation, which is composed of inorganic and organic particles, bacteria, and tissue remnants. The successful endodontic treatment concedes the removal of

debris and smear layer from the root canal system. If not done appropriately and the smear layer removal is left incomplete, the antimicrobial agents are prevented from gaining access to the infected dentinal tubules. The usage of rotary files in primary teeth was first reported by Barr *et al.* in 1999. Literature available on the use of rotary files in primary teeth has primarily evaluated cutting efficiency, instrumentation time, and shape of the prepared canals.^[3]

Ample studies were carried out on permanent dentition to evaluate the cleaning efficacy of these rotary file systems. However, very few studies were reported in the literature regarding their usage in primary teeth.^[1,3] To rationalize the use of rotary files in pediatric endodontics, the present *in vitro* study was conducted to compare the cleaning efficacy of ProTaper, K3, and Hero 642 rotary file systems in deciduous teeth at coronal, middle, and apical thirds in terms of debris and smear layer removal using a scanning electron microscope.

MATERIALS AND METHODS

After obtaining the patient informed consent, thirty freshly extracted human primary anterior teeth were selected for the study. Teeth with at least two-thirds of intact roots and no evident developmental defects/anomalous morphology were included in the study. These teeth were extracted from healthy children as they were retained beyond the normal time of exfoliation, whereas the teeth showing radiographic evidence of internal resorption or root canal obliteration and grossly decayed teeth were excluded from the study.

After attaining the institutional ethical committee approval (Pr. 34/IEC/SIBAR/2015) regarding the study design, the selected teeth were divided into three groups of ten teeth each according to the file systems used: Group I – ProTaper (Dentsply Maillefer, Asia), Group II – K3 (SybronEndo, Mexico), and Group III – Hero Shaper (MicroMega, France), respectively.

The selected teeth were mounted vertically in impression compound up to the cervical region. The coronal access cavity was prepared using a round diamond bur, and the canal patency was evaluated using #15 hand K-file. Working length was determined using radiovisiography for individual teeth.

In Group I, samples were instrumented with ProTaper in the following sequence: SX – for coronal flaring and S1, S2 – shaping the canals up to the estimated working length and finished with F1 and F2 files. Group II samples were instrumented with K3 SX in the following sequence: 0.10 – orifice shaper, 0.08 – one-third of working length, and 0.06 up to the estimated working length, whereas in

Group III samples, Hero Shaper 642 file systems were used in the following sequence: 0.06–20 for coronal enlargement, 0.04–20 – two-third of working length, and 0.06–25 up to the predetermined working length.

For all the three file systems, a standard diameter of 0.06–25 was used for apical enlargement. Biomechanical preparation was done with predetermined rotary file systems with EDTA gel lubrication following the manufacturer's instructions for each file system in crown-down technique. Later, irrigation of the canals was done with copious amount of saline and 5.25% of NaOCl following the use of each file and finally dried with paper points. Each of these instruments was discarded after usage for five subsequent times.

The teeth were sectioned at the coronal portion using a diamond disc. Two longitudinal grooves were prepared on the midline of palatal/lingual and buccal surfaces of each root using high-speed handpiece with a diamond disk to facilitate vertical splitting. Later, they were separated into two halves using chisel and mallet. The section with the most visible part of the apex was conserved for examination under the scanning electron microscope. The sections were then allowed to air dry in a desiccator at room temperature and attached to coded metal stubs and sputter with 10-nm/m gold–palladium alloys. These sections were further examined under scanning electron microscope, and photomicrographs were taken at $\times 200$ and $\times 2000$ magnification at the coronal, middle, and apical thirds. The geometric center of each third was observed and separate evaluations were recorded for debris and smear layer removal by means of the Numerical Evaluation Scale which was put forth by Hülsmann *et al.*, 1997.

The whole procedure and scoring was performed by a single operator. To ensure intra-examiner consistency, the photomicrographs were randomly evaluated by a second investigator who was blinded to the groups and was trained prior to the recording. As there was no statistically significant variation in the values between the two examiners ($P < 0.05$), the scores recorded by the first operator were only considered and the values obtained were tabulated and statistically analyzed using SPSS (version 18). Kruskal–Wallis ANOVA test and Mann–Whitney *U*-test were used to determine the inter- and intragroup difference, with a significance level of $P < 0.05$.

RESULTS

Results revealed that less amount of debris scores were detected at the apical third of root canals in all three groups compared to coronal and middle thirds, which is highly

significant [$P < 0.01$; Table 1]. The ProTaper and K3 (2.6) instruments showed less debris score at apical third of root canals which is statistically significant when compared to Hero 642 (3.6) rotary instruments [$P < 0.05$; Table 2].

In terms of smear layer, no significant difference ($P = 0.19$) was apparent in coronal, middle, and apical thirds of Group I, but significant difference was noted in Group II and III [$P < 0.05$; Table 3]. Smear layer removal efficacy at the apical third of root canal was superior in Groups I and II (3.70) compared to Group III samples (5.0), which was statistically significant. In the middle third, Hero 642 showed a lesser smear layer score (2.0) when compared to Groups I and II, which is highly significant statistically ($P < 0.01$), whereas no significant difference was noted between the three groups in the coronal third [Table 4].

DISCUSSION

The complexity of root canals in primary teeth makes it a challenge and time-consuming in children, especially during the preparation of the canal. Thus, rotary files are considered more convenient and appropriate to facilitate their use in root canal treatment in children. Canal preparation is done to debride the walls and is considered imperative for primary root canal treatment. Even though the principle behind the mechanical cleaning and shaping of root canals is analogous for both primary and permanent teeth, careful handling is required for narrow and fine canals of primary teeth. Anterior primary teeth with relatively straight canal morphology were selected for standardization in the present study.^[3]

Vaudt et al.^[5] reviewed that individual design features affect the performance of NiTi rotary instruments. Various instrument designs with noncutting tips, different cross-sections, radial lands, and tapers are now available to improve the working efficiency.^[6] Among them, ProTaper, Hero Shaper, and K3 systems have been selected for this study because they have different cross-sectional configurations and variable cutting efficiency and all the three systems were made of the same material (NiTi).

For the preparation of root canal, crown-down technique was used as it reduces friction between instruments and forms a smooth funnel shape that allows deeper penetration of needles and irrigating solutions during instrumentation and minimizes the risk of instrument separation.^[7]

All endodontic instruments create dentin debris and a smear layer as a consequence of their action on root canal walls.^[8,9] Debris is demarcated as dentin chips and the residual vital or necrotic pulp tissue attached to the root canal wall is

infected in most of the cases. Therefore, the risk for bacterial contamination increases due to the presence of debris that ultimately leads to endodontic failure.^[10] Smear layer is a thick surface film of 1–2 μm containing dentin debris, bacteria, and residual pulp tissue that remains on the dentinal walls during root canal instrumentation. Complete removal of smear layer and debris facilitates the diffusion of the irrigants/medications to the root canal system, thereby improving the adaptation of the filling materials to the root canal dentin which in turn reduces the apical and coronal microleakage.^[11]

Under the scanning electron microscopy, $\times 200$ magnification was employed for scoring debris as it offers a wider view, thus permitting us to detect large fragments of dentinal debris. Whereas $\times 2000$ magnification was used for scoring the smear layer as higher magnification covers very small surface and gives accurate information, it also allows proper visualization of the dentinal tubule openings.^[12]

It was observed that irrespective of the file system used for instrumentation, the prepared root canals exhibited maximum debris and smear layer score of 5 in few examined areas, indicating that cleanliness was not thorough due to self-centering and superelasticity of rotary instruments. Irrespectively, as the instrument remains in the center of the canal due to its rotating movement, all the areas are not being instrumented equally.^[13,14]

Comparatively less debris scores were obtained at the apical third of prepared root canal with the three selected systems of rotary files compared to coronal and middle thirds. Taha *et al.*,^[15] Rahimi *et al.*,^[16] and Júnior *et al.*^[17] also reported less debris scores at an apical third of root canals. The probable explanation for this could be the oval shape of the root canal in the coronal, middle third and a round shape as it proceeds apically.^[18] The dentin particles removed from the canal wall are carried coronally by flutes of the file, due to the use of rotary files with round cross-section. This removal was apparently less effective when the canal is oval in cross-section. The oval-shaped canal space hampers the working file being in touch with all the surfaces of root dentin. In such conditions, the debris that is carried coronally or being contained and packed in the file's flute space, gets packed actively into the area with the least resistance. It is conceivable to hypothesize that dentin particles were actively packed into soft-tissue remnants in unprepared areas that are usually resistant to the irrigation with syringe and needle.^[4] In contrary to the present study, previous standard error of the mean studies reported that the amount of smear layer and debris is greater at the apical third than compared to the middle and

coronal thirds of the canals.^[19] Kadhom and Al-Hashimi^[18] reported that ProTaper rotary file system shaped a clean canal at the coronal and middle thirds but was incapable of removing the debris at a similar rate at the apical third of the canal. However, studies that are correlated to primary teeth found no significant difference in the cleaning capacity of rotary instrumentation techniques at all the three areas of root canal based on dye penetration method.^[19,20] The difference in the outcome among various studies could be due to the difference in tooth selection, rotary instruments used, technique followed, irrigation solutions used, and the operator's performance.^[20]

Pertaining to the smear layer removal efficacy, the present study showed a significant difference in the middle third between the three groups. The reasons for removal of more amount of smear layer with Hero 642 and K3 NiTi files include triangular blade design with sharper edge and the usage of more number of instruments with chelator (EDTA) for canal preparation.^[21]

At the apical third, significant difference was observed between the three groups. ProTaper and K3 showed a significant increase in cleaning efficacy both in terms of smear layer and debris removal when compared to Hero 642. This might be attributed to cross-sectional design with a slight positive rake angle and increased helical angle from tip to handle in K3 file system.^[22] ProTaper instruments exhibit a unique variable taper design with a triangular cross-section and reduced radial lands that might allow the file to move freely within the canal and contribute to more aggressive and unconstrained cutting.^[21]

On the contrary, a study conducted by Amritha and Sureshchandra^[22] showed that K3 instruments left more debris and smear layer compared to Hero 642 instruments. The explanations for the result might be due to individual variations within the instruments and "to the core" adherence with manufacturer's instructions.

The factors to be considered while selecting rotary file systems for primary teeth include appropriate rotary instrumentation with lesser cutting efficiency and proper irrigation. A thorough knowledge and clinical expertise of the rotary system is also essential to avoid perforation of thin dentinal walls and apical extension. Further studies are recommended using different instrumentation techniques together with irrigants in the root canals of primary teeth.

CONCLUSION

- All the three file systems showed comparatively less debris scores at the apical third portion when compared to middle and coronal thirds. However, ProTaper and K3 file systems showed better debris removal compared to Hero 642 at the apical third
- In all the three groups, coronal and middle third areas showed less smear layer scores when compared to apical third. Hero 642 and K3 NiTi files displayed better smear layer removal at the middle third when compared to ProTaper NiTi files
- ProTaper and K3 files exhibited significantly better cleaning efficacy in terms of smear layer and debris removal in the apical third when compared to Hero 642 rotary file system.

ABSTRACT

Aim: The objective of the study is to compare the accuracy of bite marks on an inanimate substance (fruit) and a living tissue (skin) using digital analysis.

Methodology: A cross-sectional study was conducted involving 15 volunteers. The registered bites of individuals on inanimate object (fruit) and living tissue (skin of forearm) were photographed with the American Board of Forensic Odontology scale No. 2 in the view field immediately after the production of bite marks. Dental casts of the individuals were obtained and photographed out of which computer-assisted overlays were generated, and analysis was carried out digitally using Adobe Photoshop version 7. Statistical analysis was performed using IBM SPSS software, version 22.

Results: Skin had a comparable accuracy to that of an inanimate object which is statistically attested.

Conclusion: The source of bite marks, the substrate onto which they are generated and the technique of lifting the bite imprints serve as important tools in analysis.

Keywords American Board of Forensic Odontology guidelines, bite marks, Forensic odontology.

I. INTRODUCTION

Bite marks are often observed at crime scenes on various parts of the human body, although they are more common in certain parts of the body.¹ In addition, no body part is immune to bite marks.² These marks are not uncommonly observed in physical assault cases³ but are more common in sexual assault cases⁴ and are observed in both homosexual and heterosexual cases. These pieces of evidence have been used successfully to prosecute offenders.⁵⁻⁷ Bite marks have also been observed on various edible leftovers at the crime scenes,⁸ and these bite marks have also been used as evidence for identifying the criminals. Bite marks on inedible objects have also been reported,⁹ including on soap¹⁰ and bullets.¹¹ Bite marks have also been studied on clay,¹² and one case has been solved based on bite marks on clay.¹³ According to Pretty and Turnbull, the central dogma of bite mark analysis is based on two assumptions.¹⁴ The first is that human teeth are unique, and the second is that sufficient

detail of the uniqueness is rendered during the biting process to enable identification. Various experimental studies have been conducted on various food items, human skin and animal skin to determine similarities and dissimilarities of the bite marks and the teeth of the volunteers. Skins of dogs, pigs and sheep have been used to study bite marks.¹⁵⁻¹⁷ Studies have also been performed on wax,¹⁵ chewing gum⁷ and clay^{12,13} to develop better methods. Computers have also been used for this comparison,¹⁸ and 3D studies have been conducted¹⁹ using scanning electron microscopy.²⁰ Several studies have even used radiographs, including computed tomography (CT) scans, to compare bite marks.^{21,22} Bite marks are lifted using various photography techniques and other materials.²³ According to West et al. photographs of bite marks should be obtained as early as possible because of changes due to vital reactions.²⁴ According to McNamee and Sweet, the use of digital cameras has the advantage that it could provide instant preview and does not require scanning of the photographs.²⁵ Reflected ultraviolet imaging techniques may be the future of recording of evidence²⁶ and may be used for bite marks, as well. Casts of the volunteers, suspects and offenders have been made using standard techniques, and the casts have been compared using various methods with different types of overlays and varying success rates. Different techniques for preparing the transparent overlays are used to determine the usefulness of various methods. The data available have been questioned because they have been obtained using animal skin or skin from a small number of volunteers.^{15,17,27,28} West et al. felt that bite marks on human skin can be experimentally created to a level that permits comparison to bites delivered in combative or life threatening situations, and more research is needed using living subjects to explore a variety of experimental situations.²⁴ Although clay may not be observed to have bite marks in actual cases, the American Board of Forensic Odontology advises to use clay as the test bite media.²⁹ With various advantages and disadvantages, bite marks appear to be useful evidence for the identification of the perpetrator.³⁰

AIM OF THE STUDY

This study aims at the evaluation of the bite marks for analysis on a living tissue like skin and an inanimate object like fruit. The objective of the study being the appraisal of the accuracy of registered bite marks on respective substrates using digital analysis.

II. METHODOLOGY

Fifteen volunteers participated in the study and informed consent was obtained. The individuals participating in the study were asked to bite on an inanimate substance such as fruit with a pressure sufficient for the bite imprints to be generated with a care that the food substance (fruit) is not sheared. The bite marks thus imprinted on the surface of fruit were recorded using a camera immediately with a care that the registered bite marks were neither distorted nor deteriorated placing the American Board of Forensic Odontology (ABFO) scale No. 2 in the view field immediately after the production of bite marks to generate life-size images for analysis. The volunteers were then made to bite on their forearm after disinfecting the site. The registered bites were photographed in a similar procedure placing ABFO scale No. 2 in the view field immediately after the production of bite marks. Dental casts of the individuals were obtained using alginate impression material and dental stone. They were photographed and all the life-size images were collected with the reference scale in the field of view. The images were then subjected for digital analysis using Adobe Photoshop (Version 7). The overlays obtained from bite marks on living tissue (hand) and the inanimate object (the fruit) were compared individually with the overlays of dental casts by superimposition method.[4] When the overlays of incisal edges and cuspal tips of all the anterior teeth were apparently superimposed on to the ones generated from bite mark overlays with the alignment of each tooth and anterior arch as a whole, a Grade A was given. When the overlays were comparatively superimposed but not accurate in terms of alignment, a Grade B was assigned. No single tooth in an arch among the registered teeth in a bite mark overlay is superimposed onto the ones on dental cast; a Grade C was allocated. The grades obtained separately on living tissue and an inanimate object were compared for the accuracy of the objects for bite marks production and their analysis. The collected data were analyzed with IBM SPSS statistics software 22.0 Version. To describe the data descriptive statistics frequency analysis, percentage analysis was used. To find the significance in categorical data, Chi-square test was used. In the above statistical tools, the $P < 0.05$ is considered as significant level.

III. RESULTS

In the present study, evaluation of the maxillary bite imprints on skin asserts that the percentage of overlays with Grade A superimposition was 20%, Grade B accounts to be 24%, and Grade C was found to be 56%, whereas on fruit (inanimate object), the percentage of overlays with Grade A superimposition was 56%, with Grade B the percentage was 24%, and Grade C accounted to be 20%. Evaluation of the mandibular bite imprints on skin

asserts that the percentage of overlays with Grade A superimposition was 20%, Grade B accounts to be 32%, and Grade C was found to be 48% [Table 1, 3], whereas on fruit (inanimate object), the percentage of overlays with Grade A superimposition was 56%, with Grade B the percentage was 36%, and Grade C accounted to be 8% [Table 2, 4]. Although clinically, the percentage of distribution asserts that the fruit has a better accuracy in registration and analysis of bite marks, the statistical analysis was not in accordance with the same ($P > 0.05$).

Table 1- The percentage of frequency among three different grades of maxillary and mandibular bite imprints on skin

Grade	N (%)
Maxillary	
Grade A	5 (20.0)
Grade B	6 (24.0)
Grade C	14 (56.0)
Mandibular	
Grade A	5 (20.0)
Grade B	8 (32.0)
Grade C	12 (48.0)

Table 2- The percentage of frequency among three different grades of maxillary and mandibular bite imprints on fruit

Grade	N (%)
Maxillary	
Grade A	14 (56.0)
Grade B	6 (24.0)
Grade C	5 (20.0)
Mandibular	
Grade A	14 (56.0)
Grade B	9 (36.0)
Grade C	2 (8.0)

IV. DISCUSSION

The exact identification of a living person using individual traits and characteristics of the teeth and jaws is the basis of forensic science.³¹ The bite marks left on a person may be used to identify the perpetrator. Bite mark identification is based on the individuality of a dentition, which is used to match a bite mark to a suspected person. One can exactly match the bite marks to the accused biter's dentition.³² The most important step in bite mark analysis is to recognize a patterned injury as a human bite mark followed by pattern analysis of the bite mark which provide the individual information about the suspect or an offender and relate the person who is involved in the crime. Bite marks with high evidence value that can be used in comparisons with the suspects' teeth will include marks from specific teeth that record different characters. The surface abrasion or sub-surface haemorrhage caused by human bites appears as an arch. They are caused by the incisors, canines and premolars. Contusions are the most common type of bite mark. It can be determined from the type of bleeding under the skin whether the victim was alive or dead at the time the bite mark was delivered.^{33,34} Human tissue has been described as one of the least dependable substances for recording bite marks.³⁵ In a study by Gorea et al., skin of the volunteers was used, and it was observed that a match was possible in 60% of cases. The reason for the higher percentage of identification could be contributed to a different classification from that of the present study and a very small sample size (only 25 cases). Whittaker reported that matching of the bite marks on animal skin corresponded in only 76% of the cases.¹⁵ The percentage of nonsuperimposed overlays on the fruit in maxilla was 20% and on mandible 8%. Although stated in the study by Gorea and Jasujaet al. that exanimate object like clay has a better accuracy, this imprecision of mandibular overlays on fruit can be attributed to the fact that the quality of bite imprint is not only determined by the type and consistency of the substrate but also the biting process as a whole.¹³ The variability in the degree of superimpositions among maxillary and mandibular bite imprints can be attributed to the bite mechanism which is when the teeth apply pressure on the substrate with a varied force.³⁶ It begins with closure of mandible, followed by a negative pressure from the suction of skin or any other substrate, and the tongue thrust from the opposite direction; therefore, there would be projection of teeth edges and palatal surfaces.³⁷ However, in our study, patterns from other mouthparts or alterations in the bite patterns due to the pressure from other mouthparts was not perceived since all the participants were elucidated the kind of bite imprints appropriate for their analysis and the agendum was subjective. When an individual bites something, the

superior teeth stabilize the object, while the inferior teeth try to cut it. The indentation created by the superior teeth is significantly important to obtain information such as dental alignment, size, and shape of dentition.³⁸ The factors which influenced the accuracy of bite mark analysis in our study were physical nature of the foodstuff, the biting force with which bite mark was done. The time lapse in collection of the imprints was negligible which serves as an important factor when perishable substances are used for bite mark analysis.

V. CONCLUSION

The importance of bite marks and their analysis in forensics is well asserted. The source of bite marks from which they are produced, the substrate onto which they are generated and the technique of lifting the bite imprints serve as important tools in analysis and identification. Although inanimate objects serve as a better sources for analyzing bite marks, when collected immediately with an appropriate technique skin has an equivalent accuracy in bite mark analysis.

ABSTRACT

Over the years, there have been numerous studies regarding the restoration of primary teeth. Some of them recommended the need of a full coverage crown for restoration over the conventional class I, class II and class V restoration, others pointed out over the need of aesthetic restorations for Pediatric patients. As the technology advanced, the level of parental satisfaction with the conventional stainless steel crowns lowered, this made the Pediatric dentists to search for an aesthetic restoration for the decayed primary tooth like zirconia crowns, pediatric jacket crowns, strip crowns, glass tech crowns etc. The advent of such advanced techniques, devices and material helps in creating beautiful restorations which help children and adolescents improve their self image as we know that the child esthetics is the guide to the adult esthetics.

Keywords stainless steel crowns, aesthetic, strength, zirconia, strip crown.

INTRODUCTION

The presence of decayed or deformed teeth leads to a negative impact to infants and adolescents due to rejection by their peer group because of unpleasant dental appearance, which is reflected in their adulthood. Seehraj el al stated that dental appearance of a child influences bullying in school which has its long term and short term psychological impact.¹ Besides that, decayed tooth also leads to development of parafunctional habits like tongue

thrusting, reduced masticatory efficiency, loss of vertical dimension of occlusion and speech problems.²Humphrey in 1950 introduced stainless steel crowns, which proved to be a boon to clinical Paediatric dental practice. The stainless-steel crowns are most frequently used in deciduous dentition than permanent dentition because of the reason that even a small carious lesion can destroy the integrity faster in deciduous dentition than in the permanent teeth. But the lack of aesthetics, unacceptable metal appearance to parents, patient and beholders, limited their use to posterior teeth only.³Due to this Open faced stainless steel crowns evolved, which involves the placement of tooth coloured material by fenestrating the labial aspect of the stainless steel crowns, this combined aesthetics along with durability to stainless steel crowns.⁴ Apart from the above mentioned crowns more aesthetic crowns includes Bonded crowns, this includes Polycarbonate crowns. These are heat bonded acrylic resins mainly used to restore anterior teeth, these are more aesthetic than Stainless steel crowns, easy to trim and can be adjusted using pliers.⁵ Another aesthetic approach is Strip crowns, which constitutes the most commonly used variety of Bonded crowns. These are filled with composite and bonded to tooth this imparts superior aesthetics. However, it is technique sensitive and any lapses in patient selection, isolation, tooth preparation and resin bonding can lead to failure.⁶Pedojackets, new millennium and glass tech are other forms of Bonded crowns. Ongoing researches in the field of material sciences have led to the introduction of preformed All-Ceramic and Zirconia crowns in Paediatric Dentistry. It has similar mechanical properties like metals along with tooth coloured appearance and extreme biocompatibility.⁷

CLASSIFICATION OF CROWNS

Paediatric crowns can be broadly classified as luted or bonded depending upon the mechanism of adhesion to the tooth, in case of luted crowns the adhesion is purely physical or mechanical where as in bonded crowns, the crown is bonded to the etched enamel surface, thus establishing a mechano-chemical adhesion to the tooth surface.⁸ (Figure 1)

STAINLESS STEEL CROWN

Stainless steel crowns (SSC) are considered to be the most durable, economical and reliable for restoring severely carious and fractured primary teeth. They are easy to place, fracture proof, wear resistant and attached firmly to tooth until exfoliation.¹

Types of stainless steel crowns:

Stainless steel crowns type is based on shape:

Untrimmed crowns

The untrimmed crowns are neither trimmed nor contoured, need a lot of adaptation and are time consuming. Example of untrimmed crowns is Rocky mountain.

Pre-trimmed crowns

The pre-trimmed crowns are non-contoured but festooned to follow a line parallel to the gingival crest. They still require contouring and some trimming. Examples of pre-trimmed crowns are Unitek, 3M Co., St.paul, MN

Pre-contoured crowns

The pre-contoured crowns are festooned and are also pre-contoured though a minimal amount of festooning and trimming may be necessary. Examples of pre-contoured crowns include Ni-Chromium.

PRE-VENEERED STAINLESS STEEL CROWNS

Preformed metal crowns (stainless steel / nickel chrome crowns) out-performs the intra coronal restorations in terms of longevity as are reliable and durable. Pre-veneered stainless steel crowns provide full coverage, durability, easy placement and aesthetics. These crowns are nickel chrome crown having an aesthetic facing, mechanically and / or chemically bonded.

OPEN FACED STAINLESS STEEL CROWN

To take advantage of the strength and durability of preformed stainless steel crowns with improved aesthetics Open Faced Stainless Steel Crowns were developed. Here a composite material is bonded on the labial surface of Stainless steel crown. Open faced stainless steel crowns can be used for both anterior and posterior teeth, this involves creation of a window or labial fenestration on the cemented crown, followed by removal of the cement used for crown cementation, to make the underlying tooth tissue visible, in cases where the only little amount of tooth tissue is left and the crown is cemented using glass ionomer cements,⁹ the composite can be bonded directly over the cement after creating a few retentive grooves around the gingival areas of the crown.¹⁰

ZIRCONIA CROWNS

Zirconium oxide crowns have exceptional properties such as high flexural strength and fracture toughness, high hardness, excellent chemical resistance and good conductivity ions. Different oxides, such as Yttrium Oxide (Y₂O₃), Calcium Oxide (CaO) or Magnesium Oxide (MgO), can be added to Zirconia to stabilize it. Cyclical stresses are also well tolerated by this extremely biocompatible material. In this way it can be said that this material has the potential to be used for larger restorations and in the molar area.¹¹

POLYCARBONATE CROWNS

Polycarbonate crowns are heat-molded acrylic resin shells that are adapted to teeth with self cured acrylic resin. Though poor in strength, the polycarbonate crowns provide excellent aesthetics as compared to the conventional stainless steel crowns. They can be good restorations in anterior teeth as it presents much less masticatory load as compared to posterior teeth. If combined with microglass fibres, the microglass fibres improves the impact strength and flexibility of the crown.

STRIP CROWNS

Pediatric Strip Crowns are transparent plastic crown forms used for restoring primary anterior and posterior teeth, these crowns accounts for the most commonly used bonded crown to restore primary anterior teeth. These are the first choice restoration for many clinicians, mainly because of the superior aesthetics and the ease of repair if the crown subsequently chips or fractures.¹² Strip crowns are an easy chair side procedure and final restorations are more compatible with gum tissue than stainless steel crowns.⁴ Presently strip crowns for primary teeth are being marketed by 3M ESPE (only anteriors) and Success Essentials (both anterior and posteriors), Dentsply professionals, Directa, Unitek Strip Crown, Nowak Crowns Nowak Dental Supplies Inc. and Carriere, MS.

PEDO JACKET CROWNS

The Pedo Jacket is a crown form similar to the resin bonded strip crown, the only difference is of the "jacket" which is made up of a tooth-colored co-polyester material and is filled with resin material and left on the tooth after polymerization instead of being removed. These crowns are thin yet have a strong inter-proximal wall which allows an easy placement of

multiple adjacent restorations with a minimum amount of tooth reduction. These crowns are cost effective and are easily sized and trimmed with scissors and can be readily adapted over irregular teeth. Polyester is a synthetic polymer made of purified terephthalic acid (PTA) or its dimethyl ester dimethyl terephthalate (DMT) and monoethylene glycol (MEG).¹³

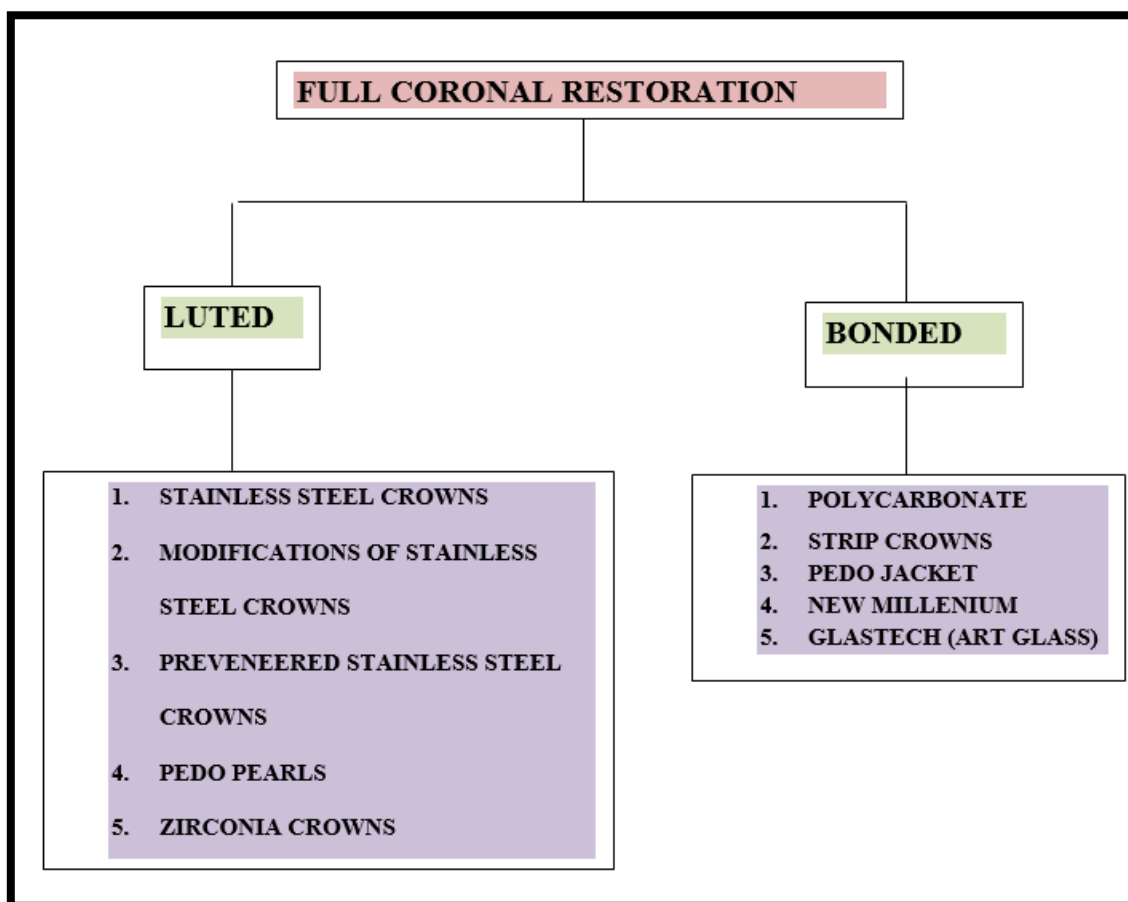

NEW MILLENNIUM CROWNS

This crown is another modification of strip crowns and similar in form to the Pedo Jacket crowns except that it is made of a laboratory-enhanced composite resin material. In contrast to the Pedo jackets these crowns can be easily finished and reshaped with a high-speed bur and a greater degree of aesthetics can be achieved. These Crowns are being marketed by success essentials, space maintainers laboratory and are available for all anterior and posterior teeth.¹⁴

PEDO PEARL CROWNS

It is a metal crown form similar to a stainless steel crown, but it is completely coated with a tooth-colored epoxy powder i.e. Polytetrafluoroethylene (PTFE), a synthetic Fluoropolymer in specific. These crowns are made of heavy gauge aluminum instead of stainless steel because the epoxy coating adheres much better to the aluminum. These crowns are being manufactured by Pedo Pearls, 6111 FM 1960 West Suite 215 Houston, TX 77069, USA, for Anteriors. Its available in sizes 1- 4 and in universal form, for Posterior 5,6.¹

Figure 1- Classification of Paediatric Crowns

GLASS TECH CROWNS

Glass tech crowns are the preformed crowns made of Artglass, which is a polymer glass, it gives a natural feel, bond ability and kindness associated with composite but the esthetics and longevity of porcelain. It is color stable, wear of polymer glass is similar to enamel, kind to opposing dentition, plaque resistant and without any composite interface. The unique filler materials of microglass and silica are proposed to provide greater durability and excellent esthetics than the strip crowns.¹²

RECENT ADVANCES IN PAEDIATRIC CROWNS

Flex crowns

They are white faced, overcome the aesthetics problems associated with plain stainless-steel crowns. These crowns can be manipulated and handled similar to the conventional stainless-steel crowns.¹⁵

Life like paediatric crowns

They are highly durable and aesthetically translucent thus are claimed to deliver natural tooth like appearance to the restored tooth. These crowns have a stable color which does not stain, discolor or fade.¹⁶ Fuks AB et al., assessed the clinical performance of esthetic crowns and compared these to conventional stainless steel crowns, for this purpose they placed twenty two crowns (11 conventional and 11 esthetic) in mandibular primary molars obeying these criterias; the tooth was not mobile; no fistulae were present; the tooth had at least one caries free or properly restored antagonist and had to be in contact with one adjacent tooth mesially, in the case of the primary second molars or distally in the case of the primary first molars and evaluated them clinically and radiographically after 6 months and concluded that the esthetic crowns assessed had several inconveniences, as they resulted in poor gingival health, are very expensive, and, although not measured, are bulky and without a natural appearance.¹⁷

Krämer et al., evaluated the effect of thermo-mechanical loading (TML) on marginal quality and wear of different crown types for primary molars. For this purpose they used eighty extracted human primary molars. After preparation, five groups received different crowns (n=16): preformed metal crowns (3M ESPE) and NuSmile crowns (Orthodontic Technologies Inc.) were inserted as preformed metal crowns; as semi-preformed crowns Protemp crowns (3M ESPE) were luted, the specimens were subjected to 2,500 thermal cycles between 5–55°C and chewing simulation for 100,000 cycles at 50N at a frequency of 0.5 Hz. Before and after thermo-mechanical loading, impressions of the teeth were taken and replicas were made. The replicas received marginal quality evaluation under a SEM at×200 magnification and depending upon their findings they concluded that the different crown types under investigation showed a good performance concerning the evaluated parameters marginal quality and wear.¹⁸

CONCLUSION

The Paediatric dentists have the responsibility and ability to create beautiful smile for young patients. By far numerous literatures are available regarding the use and introduction of various crowns for restoring the Primary teeth but very few studies are available regarding the clinical longevity and success of these restorative technique, making it difficult to recommend any one type of restorative option over the other thus the ultimate choice of

restorative technique depends upon the operator preferences, aesthetic demands by the parents, cost and child's behaviour that affect the final outcome of which ever restorative material chosen.

Abstract

Introduction: The success of the root canal therapy depends on many factors. Loss of the tooth structure during the canal preparation leads to the fracture of the tooth. The rotary instruments were invented to put less force on the tooth during the preparation.

Hence in the present study we aim to compare the effect of three rotary file systems (Vortex Blue, VTaper, ProTaper,) with dissimilar tapers on fracture resistance of root canal treated teeth by various static and dynamic forces applied to different parts of the coronal part of teeth.

Materials and Methods: 3D printed acrylic maxillary first molar was used. The original geometry was changed and primed for using Spaceclaim software for ANSYS modeling and analysis. The three experimental groups and one control group were created. Group one was ProTaper, group two was Vortex Blue and group three was V-Taper. Young modulus and Poisson ratio of all the materials (Enamel, Dentin, Gutta-Percha, Composite) were used for ANSYS software to recognize these volumes and the constituents that are contained within these individual spaces. In this study seven total contact points were considered on the occlusal surface of the models during the chewing cycle. The Von Mises stress and maximum principal stress on the cervical region were calculated and investigated in four different cross sections of pre cervical dentin.

Results: The highest Von Mises stress was observed in the ProTaper group although V-Taper and Vortex Blue groups showed homogeneous stress distributions in the cervical regions as well. Tensile stress was concentrated on the palatal side of the palatal root and the distal portion of the distobuccal (DB) root in all the experimental groups. However, the control group had the least

amount of stressed area followed by V-Taper group, Vortex Blue and ProTaper.

Conclusions: Taper size of endodontic files seems to affect the distribution of forces along the root structure. Preserving dental hard tissue in precervical dentin significantly reduces the stress concentration in the cervical region and increases the eventual fracture resistance of the tooth.

Keywords: Root canal preparation, root fractures, Taper of the file, Rotary instrumentation

Introduction

Fracture of the Root is the third most common problem for the tooth loss only after caries and periodontitis. (1) For the clinical practice the knowledge of the biomechanics of the fracture is important for the successful treatment. The initiation and the propagation of these fracture lines can be a result of the various types of the forces.(2) The loss of the major portion of the tooth due to the preparation for the root canal may lead to the concentration of the forces and may help in the fracture propagation.(3) To avoid this, removal of the pre-cervical dentin excessively is to be avoided. (4,5)

Various rotary systems apply various types of the file systems that use files of different cross sections, sizes and shapes that have different working patterns once inside the canal. There are many studies that have described the root fractures when these rotary instruments are used. (6–8). In the study of Clark and Khademi, they have suggested that the pre-cervical dentin be protected at all the times to prevent the fracture.(9). Most of the studies done previously are studied invitro. This is because as the human teeth are tough for the standardization. (10)

Hence in our study we used FEA (Finite Element Analysis) to gain a better understanding of the effects of the cleaning and shaping process through endodontic treatment. FEA would also help in knowing the factors for initiation and propagation of cracks and fractures in root canal treated teeth. Thompson et al, stated that during the mastication, the stress at the cervical region of the tooth rises as the taper of the files increases (11). In our study we compared three commonly used files systems. V-Taper, Vortex Blue, and ProTaper are used to understand the fracture resistance after the root canal preparation to the various strains and stresses at different parts of the tooth.

Materials and methods

3D printed acrylic maxillary first molars were used in the study. For the FEA, CAD geometry of the tooth was first prepared. The replica was then scanned by a micro CT. The image was sent to the ANSYS SpaceClaim software for analysis. All the precautions were taken to simulate the original tooth morphology of the molar. We classified the replica into 4 groups. They are Group1- ProTaper, Group 2 - Vortex Blue, Group 3 - V-Taper, Group 4- Control. A conventional access cavity was made with one-degree inward taper to the pulpal floor. Canals were then prepared and designed starting at the pulpal floor and extending to the apex. The apical foramina were enlarged to 0.3 mm, and the working length was set at 0.5 mm coronal to the apical foramen. 16 mm was the length of the canals. Later the canals were filled with the GP obturating materials. Access cavity was restored with composite in the three groups. For the control group the canals were left empty and the access was filled with 2 mm of enamel and the dentin. All the materials were noted for the physical properties. The amount of the loads was

thoroughly registered. Von Mises stress was calculated in each of these elements. All the replicas were subjected to similar stresses and strains that are produced in the routine mastication. All the volumes and the amount of the displacements faced by all the replicas under similar conditions were registered. The obtained values were only compared between the groups.

Results

The Von Mises stress and maximum principal stress on the cervical region of maxillary first molar replica is calculated. In this study, the cervical region was deliberated as a critical zone. The stress distribution of the chewing force was deliberated and analyzed in four separate horizontal cross sections of the cervical region. Three cross sections were located above the pulpal floor and one below the pulpal floor at the level of buccal furcation. Von Mises stress was more at the CEJ level. The highest Von Mises stress was observed in the ProTaper group, although V-Taper and Vortex Blue groups presented homogeneous stress distributions in the cervical regions as well. The stress distributions of the maximum principal stress in the cervical region were analyzed. The ultimate loads that caused failure of dental material was considered to be 50 MPa and any amount of stress higher than that was revealed in red in all the experimental group, and it was considered detrimental to the tooth structure.

In all experimental groups, tensile stress was concentrated on the palatal side of the palatal root and the distal portion of the distobuccal root in the cross sections at the level of CEJ and the pulp chamber floor (Figure 13-14). However, the intensity of stressed areas differed among each experimental group. The control group had the least amount of stressed area in red followed by V-Taper group, Vortex Blue and ProTaper

Table 1: Comparison of the various canal preparation systems

Distance from CEJ	Protaper	V-taper	Vortex blue	Control
2.5 mm above the CEJ	325.81	321.43	357.26	318.44
0.3 mm above the CEJ	325.81	321.43	357.26	318.44
1.3 mm above the CEJ	325.81	321.43	375.26	318.44

Discussion

In the study of Kakehashi et al, they proposed that the microorganisms were the cause for the dental diseases. (12) In the root canal treatment the removal of these microorganisms will help in the healing of the tissues surrounding the periapical region. Many modifications have been made in the treatment modalities of the root canal therapy with the advent of the rotary instruments. Various studies state that the instrumentation by itself can efficiently reduce the microbial load in the root canal system by 90 % (13). But there has been no one particular instrument to fully achieve this sealing ability.

With the usage of the various rotary systems there has been much comparison of how these may impact the strength of the tooth in the long run. It has been stated in the study of Hedge et al, that the preparation of the root canal should follow the anatomy and remove as less tooth structure as possible.(14) In the various studies of Orstavik et al, Peters et al the final preparation sizes and the instrumentations had no significant variations on the outcome.(15,16). The best size of the

file that can bring about an ideal outcome is yet to be determined.

It is imperative to the clinician to not only understand the mechanics of the instruments but also to the impact of these on the strength of the tooth. With the recent rotary systems there has been a noted removal of the tooth dentin in the coronal and the radicular areas. In the study of Gher et al and Kovac et al, they have noted higher ratio of vertical root fracture in endodontically treated teeth (17, 18). Teeth that have been fractured may not be noticed for a long time by the patient and the pain may only be felt under specific conditions. Hence it is challenging for the dentist to identify and diagnose these fractures. Therefore many attempts to minimize the instrumentation as much as possible are done. If the tooth fractures while eating then the effort that was done to endodontically restore it may go in vain.

Hence in the present study we intend to compare the fracture resistance of the tooth while conserving as much as tooth possible. Maxillary first molar CAD design was used to simulate the natural masticatory forces. We selected the rotary instruments with different sizes and tapers.

The FEA was used to measure the amount of stress and strain applied on dentin near the pre-cervical area and alveolar crest of maxillary first molars. It is a critical zone that is roughly 4 mm above the crestal bone and extends 4 mm apical from the crest of the bone.

We selected the pre-cervical area as it has the: 1) The effect of ferrule, 2) the proximity of dentin tubule orifices at the CEJ, 3) the significant reduction in enamel thickness, and 4) the concentration of all masticatory forces in this area (5-11). In this study, a replica of the maxillary first molar that is endodontically treated with three different rotary instruments was generated based on micro CT.

We noted that, Von Mises stress was more on the margin of the palatal root significantly less in the V-Taper group and the control group in contrast to ProTaper and Vortex Blue. With the reduction of dentinal wall removal, the stress concentration also declined.

The ProTaper group showed the most amount of stress concentration surface area in comparison to the other groups at the CEJ level, and with the V-Taper group having the closest stress concentration to intact tooth. The foci of tensile stress were located on the palatal portion of the palatal root, the root furcation, and the distal portion of the distal root. Previous studies have shown that the maximum principal stress in the mesio-buccal root was significantly more than other areas (19).

Nevertheless, in this study, the maximum stress was on dissimilar areas possibly due to the replication of the chewing forces rather than using direct vertical forces.(20-22) The three groups of file sizes in this study had same tip size (0.25 mm), yet, their MFD at D16 are significantly different, with ProTaper being the largest file and V-Taper being the smallest near D16. Hence, within the limits of the present study, it can be stated that saving the dental hard tissue, in particular pre-cervical dentin, in root canal therapy is a feasible method to decrease the maximum principal stress and to decrease the stress concentration near this susceptible area. This was a critical area to scatter stress through the long axis of the teeth.(23-25) V-taper files are intended to decrease the amount of tooth structure removal in pre-cervical dentin to minimize the overall weakening effects of endodontic treatment.

Conclusion

In our study we intended to explain the taper of the instrument and the fracture resistance by using the Finite Element Analysis in the maxillary first molar replica. We can conclude that Taper size may effect to the fracture resistance in the cervical areas by concentration of forces. Conserving dental hard tissue will decrease the concentration of the stress in the cervical region and hence may prevent the tooth fracture. However the simulated FEA method has few limitations. Thus, the clinical implications of results obtained in our study need additional exploration on natural tooth and ideally under masticatory forces in the oral cavity.

ABSTRACT

Teledentistry in pediatric dentistry - Telepedodontics, a comparatively new field, can modify the dynamics of the dental care delivery system. Maximum of the dentists are ignorant about teledentistry, about its goals and benefits and how to get involved into it. This review demonstrates as to how teledentistry can be an actual solution for dentists and their patients.

Teledentistry gives a likely resolution to many enduring complications in dentistry, but it also faces substantial challenges. Its evolution will be contingent as much, on the struggles of the health authorities as on the combined efforts of the dental professionals.

Telepedodontics can meet the dental care needs of the underserved in the rural areas of India and it can guarantee the good oral health of the children in schools and child care centers. Telepedodontics gives new opportunities for dental education by providing an easy access to primary care professionals for effective consultation, thus serving in piloting effective postgraduate education and continuing dental education programs.

Key Words: Telepedodontics, Teledentistry, Preventive Dentistry, Pedodontics.

INTRODUCTION

Dental care is being continually altered by the opportunities which are delivered by technology and telecommunication [1]. Tele dentistry is a comparatively new field that syndicates telecommunication technology and dental care. Due to the huge development of technological proficiencies, teledentistry owns the potential to basically change the current practice and the face of the dental care [2]. The term “teledentistry” was used in 1997, when Cook defined it as “the practice of using video-conferencing technologies to diagnose and to provide advice about the treatment over a distance” [3]. ‘Teledentistry’ permits a whole new way of giving specialist advice. By the use of telecommunication and computer technologies, it is now conceivable to deliver interactive access to specialist views that are not limited by the limitations of either space or time.

The referring dentist logs into a secure web-server and fills in the patient’s details, the detailed reasons for the consultation, the chief complaints and the provisional diagnosis information and attaches the digital intra-oral images and the scanned digital dental radiographs. The specialist then logs into the secure web server, analyses the case and proposes his diagnosis and treatment plan within a specified time.

TELEPEDODONTICS AND ITS APPLICATION IN DENTAL EDUCATION OF THE PEDODONTISTS

The role of Telepedodontics in education can be divided into two main categories: self-instruction and interactive video-conferencing.

The Web-based, self-instruction educational system contains evidence that has been established and deposited before the user opens the program [4]. The benefit of this system is that the user can regulate the speed of the learning and can read the material many times at convenient times [5]. Johnson and Schleyer [6, 7] considered the Web-based dental continuing education and assessed them on the basis of a set of well-designed guidelines by applying the Design of Educational Software. Spallek and colleagues [8] lead a survey of the applicants in several Web based dental CE courses and found that absence of in person communication with their colleagues and mentors could result in disappointment.

Interactive video-conferencing may be lead via POTS (plain old telephone service), satellite, ISDN, Internet or Intranet. Interactive video-conferencing comprises both a live interactive video-conference with a proper camera set up where the patient's data can be transmitted; and associated information (such as the patient's medical history, radiographs, etc) that can also be referred before or at the similar time (for example, via fax) as the videoconference. The benefit of this type of education system is that the user can receive an instant response [5].

ROLE IN PEDIATRIC AND PREVENTIVE DENTISTRY

Telepedodontics is particularly beneficial for children. Applying teledentistry, children's teeth were checked for early childhood caries, thru which it was reported that all children enjoyed seeing their teeth on the computer screen. Dental imaging was assumed as a game by them, quite than as a dental examination. Furthermore, as no instruments are used and the camera head does not need to be put in far into the child's mouth to obtain dental images, there was less menace of uncooperative behavior by the very young child or toddler than that posed by a routine dental examination. Child comfort is also enhanced when the teledentistry examination is done in a known environment, as compared to a clinic. This lead to in children being more enthusiastic and co-operative at the imaging and recording processes. Furthermore, guardians and children saved the time off work or school for travel, and a child can be tracked effortlessly to conclude whether treatment has been taken, or if an emergency assessment is wanted.

Kopycka-Kedzierawski DT and Billings RJ presented that teledentistry is more or less equal to visual/tactile examinations for dental caries screening in pediatric patients.[9] Kopycka-Kedzierawski DT *et al.* recommended that teledentistry offers a possibly well-organized means of screening high-risk preschool children for signs of early childhood caries.[10] They successfully established a teledentistry project recognized in inner-city child-care centers in Rochester, NY.[11] Amavel R *et al.* detailed that distant diagnosis of children dental problems based on non-invasive photographs set up a valid resource.[12] Kopycka-Kedzierawski DT *et al.* validated that the intraoral camera is a possible and potentially economical substitute to a visual oral examination for caries screening, particularly early childhood caries, in preschool kids attending childcare centers.[13]

TELEPEDODONTICS AND ITS USE IN RURAL AREAS FOR THE PEDIATRIC PATIENTS

In country areas, where there is a scarcity of specialists, the deficiency of comprehensive and sophisticated health care is a problem. Telepedodontics can increase the accessibility of the specialists to the village and underserved groups for their dental needs, also lessening the time and the price which are related with the specialty sessions [14].

Altering the service delivery method may also certainly affect the viability of a rural practice. Separation from peers, specialists, and continuing education opportunities are the undesirable aspects of a rural practice. Providing dental care in a salaried arrangement allows one to meet

the financial obligations while learning to build the competences which are expanded with experience in care delivery without incurring additional debt. It also allows one to model the experience of existing in a rural setting without requiring to a permanent relocation.

TELEPEDODONTICS AND ITS ROLE IN POSTGRADUATE EDUCATION IN THE DEPARTMENT OF PEDODONTICS AND FOR DENTAL PRACTICE

Telepedodontics can serve as a good tool for teaching postgraduate students and for giving current updates for the practicing dentists.

In shared video-conferencing, the patient data is assessed first (with or without the patient's presence), that lets for the communication and feedback among the teacher and the students. The patient cases can be studied thoroughly and at the students' speed. The cases can be deliberated in detail after all the clinical data have been composed and conveyed, without the patient being there at the arranged meeting. This improves the students' enthusiasm and offers new learning prospects for the dental students and the practicing dentists.

THE ROLE OF TELEPEDODONTICS IN SCHOOLS AND CHILD CARE CENTRES

It is the essential to develop models for schools and child care centers in our nation to use Telepedodontics to raise the access to dental care for the kids. Schools and child care centers play an important role in guaranteeing the optimal oral health of the children through:-

- Screening for dental problems beforehand these become emergencies [15].
- Assisting children in handling chronic illnesses.
- Linking children and their families to the required health and social services.
- Giving urgent care.

Pediatric dentists at the University of Rochester use the images of toddlers to classify those with early childhood dental caries. A study of the program found that nearly 40% toddlers had tooth decay. The timely detection of such decay can stop the child from painful and monetary trauma, visits to the emergency treatment room, and eventually, extractions of the teeth [16].

Telepedodontics may serve as a tool to supplement and multiply the capacity of school and child care centers to meet the children's dental care requirements by expending technology to link to the health providers at another location.

SCOPE OF TELEPEDODONTICS IN INDIA

India has opened up to Telepedodontics to address many issues which are being confronted by the healthcare delivery system, like insufficient health organization and clinical services, paucity of competent doctors, the nearly non-availability of specialist care, the late detection of the illness, the deferral in the conveyance of the treatment due to the greater time which is essential for the transport of the patients to city healthcare facilities and the delivery of healthcare by inexperienced primary healthcare service providers [17].

In 1999, the Department of Information Technology, the Ministry of Communications and Information Technology (Government of India) propelled a pilot project which was titled, 'Development of Telemedicine Technology', with the aim of strengthening the national healthcare delivery system [18]. The key terms of the project comprised [19].

- To recognize the suitable technological tools and facilities which are essential to implement telemedicine technology at the three leading hospitals in the northern parts of India, viz., All India Institute of Medical Sciences (AIIMS), New Delhi, the Post Graduate Institute of Medical Education and Research (PGIMER) at Chandigarh and the Sanjay Gandhi Post Graduate Institute of Medical Sciences (SGPGIMS) at Lucknow (Uttar Pradesh).
- To improve and perform system integration to permit telemedicine technology and for

starting telemedicine services (teleconsultation and teleradiologic services for the specialties of radiology, cardiology and pathology and teleeducation) at three tertiary level hospitals.

- To train clinicians in the use of telemedicine technology.

In India, where a bulk of population lives in countryside areas and where healthcare amenities are inadequate, Telepedodontics can have a significant contribution in linking the gap between the demand and the supply.

FUTURE PROSPECTIVES OF TELEPEDODONTICS

The advances in telecommunication have rightly enabled the dental care to assure many exhilarating modifications during the following few years [20]. Still, like any revolution, it will not be stress-free or effortless. There are definite issues which need resolution for the success of Telepedodontics. These issues comprise inter-state licensure, jurisdiction and malpractice, as well as technological, security and ethical features [21].

Several measures that can be engaged for the effective application of teledentistry are:

- The tutors of the teledentistry education courses need to be well experienced with software knowledge and they should have satisfactory teaching experience [7].
- The practitioners who are involved in teledentistry must have a license in each state in which they practice [22].
- Dentists who are involved in teledentistry must make every effort to confirm the security of their systems, as well as of any data that they may communicate. For example, data encryption, password protection and user access logs can help in discouraging most of the people and in shielding patient confidentiality [21].

SUMMARY

Dentistry, in a synergistic amalgamation with telecommunications technology and the Internet, has produced a relatively new and thrilling field that has limitless potential. Telepedodontics can be used as an appreciated tool for giving dental care in village areas, where there is a scarcity of pedodontists and a lack of complete and sophisticated health care. It can be an answer to the obstacles of dental care like the absence and price of transport, leave from work and school and to save the patient's money. Furthermore, Telepedodontics gives new chances for dental education by providing the primary care professionals with an easy access to effective consultation and by serving in directing postgraduate education and continuing dental education programs.

In spite of few problems which need to be determined, the potential of Telepedodontics is wonderful, which needs to be discovered.

Abstract

Objectives: To evaluate the level of knowledge, understanding, and impact of the coronavirus disease 2019 (COVID-19) pandemic on adult patients regarding their ongoing fixed orthodontic treatment.

Subjects and Methods: A cross-sectional and descriptive survey was conducted on 108 adult patients undergoing fixed orthodontic treatment at GSL Dental College (GSLDC), India. All the candidates were aged 18 years and above, who were in lockdown due to the COVID-19 pandemic and devoid of treatment.

Results: Among the patients 43.5% were male and 56.5% were female; 22.3% were not at all aware that the COVID-19 virus spreads quickly in a dental setup; 64.8% were definitely willing for their status disclosure and to undergo pretreatment screening; 71.3% were definitely willing to adhere to strict appointment timings for adequate sanitization of the clinical area; 60.2% thought that missed appointments during the COVID-19 pandemic would prolong their overall orthodontic treatment and affect their treatment outcome; and 51.9% were financially affected due to the pandemic.

Conclusions: Not all adult orthodontic patients were in knowledge of COVID-19 cross infection. The majority were in a state of understanding and willing to follow infection-eradicating protocols. Patients' view on overall orthodontic treatment was altered due to the psychological and financial impact of COVID-19.

COVID-19 pandemic, adult patients, ongoing fixed orthodontic treatment, lockdown

Received: 25 May 2020; **Revised:** 25 November 2020; **Accepted:** 28 December 2020

Introduction

Coronavirus disease 2019 (COVID-19), caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has become a significant public health emergency across the world, which has led the World Health Organization (WHO) to declare it as a pandemic.¹ Currently, it is believed that its interpersonal transmission occurs predominantly via respiratory droplets/secretions (cough, sneeze), saliva, and contact transmission where the virus enters the mucous membrane of the mouth, nose, and eyes.² All dental professionals, including orthodontists, are at higher risk of SARS-CoV-2 infection due to dental practices and hospitals' characteristics, which include aerosol generation, handling of sharps, and proximity to patients' oropharyngeal region.^{1,3} If acceptable safety measures are not taken, cross-contamination risk could be extreme among dentists, orthodontists, and patients.

Most countries initiated a regional or national lockdown to restrain the spread of this disease, permitting only medical and dental emergency services to continue. In many such efforts, performing of elective tasks, including orthodontic treatment, is suspended.⁴ Since fixed orthodontic treatment is a long and

continuous scheduled process, millions of patients who were already undergoing treatment have been affected. The overall treatment time might be affected due to the unknown span of this mandatory suspension. A lot of awareness and understanding of the COVID-19 pandemic needs to be emphasized for orthodontic patients, so that it does not impact their psychological well-being. For instance, most minor to moderate orthodontic problems can be taken care of through teleconsultation. However, addressing orthodontic emergencies in this pandemic might be an extra financial burden, as dental setups need to be maintained with a very high standard of sterilization, infection prevention and control protocol.

The study aims to evaluate the level of knowledge, understanding, and impact of the COVID-19 pandemic on continuing fixed orthodontic treatment in adults.

Subjects and Method

Ethical approval was obtained from the GSL Institutional Ethics Committee and GSL Research Cell, Project ID: 032020/001. A cross-sectional study design was used.

Inclusion Criteria

Adult patients aged 18 years and above who were undergoing fixed orthodontic treatment at GSL Dental College (GSLDC) during the lockdown due to the COVID-19 pandemic were included in the study.

Sample Size

The sample size calculation for the present study was done through a questionnaire-based study that considers the level of knowledge and understanding among people in different regions.⁵

Questionnaire Design

A questionnaire was devised from the key themes and concepts identified with regard to the COVID-19 pandemic (Table 1).

Table 1. Overview of the Results of the 13 Questions

No.	Question	Options	Count (%)
Q1	Are you aware that the COVID-19 virus spreads easily in the dental setup?	(a) Extremely aware (b) Very aware (c) Moderately aware (d) Slightly aware (e) Not at all aware	43 (39.8) 12 (11.2) 10 (9.3) 19 (17.5) 24 (22.3)
Q2	Are you willing to undergo treatment from an orthodontic team who were previously affected with COVID-19?	(a) Definitely (b) Probably (c) Possibly (d) Probably not (e) Definitely not	17 (15.7) 19 (17.6) 16 (14.8) 32 (29.6) 24 (22.2)

(Table 1 Continued)

No.	Question	Options	Count (%)
Q3	Are you willing to disclose your COVID-19 status and undergo pre-treatment screening before every appointment?	(a) Definitely (b) Probably (c) Possibly (d) Probably not (e) Definitely not	70 (64.8) 22 (20.4) 8 (7.4) 6 (5.6) 2 (1.9)
Q4	What is your view on visiting the orthodontic office after the COVID-19 pandemic?	(a) I will visit the orthodontist if proper infection control precautions are followed. (b) I will have some fear or doubt even though the orthodontist follows the infection control precautions. (c) I will not visit even though the appropriate infection control precautions are followed. (d) I will only visit after this COVID-19 pandemic issue is resolved.	68 (63.0) 18 (16.7) 1 (0.9) 21 (19.4)
Q5	Do you adhere to strict appointment timings for the clinical area's adequate sanitization to counter-act COVID-19?	(a) Definitely (b) Probably (c) Possibly (d) Probably not (e) Definitely not	77 (71.3) 27 (25.0) 3 (2.8) 1 (0.9) 0 (0)
Q6	Would you like to adhere to "Strictly no accompanying person" (until and unless specified by the orthodontist) for future appointments?	(a) Definitely (b) Probably (c) Possibly (d) Probably not (e) Definitely not	58 (53.7) 31 (28.7) 8 (7.4) 5 (4.6) 6 (5.6)
Q7	Do you have any pain or discomfort due to missed appointments during the COVID-19 pandemic?	(a) Severe (b) Moderate (c) Mild (d) Very mild (e) None	13 (12.0) 16 (14.8) 22 (20.4) 20 (18.5) 37 (34.3)
Q8	For unexpected orthodontic problems, which of the following options do you choose?	(a) I prefer telecommunication with the dental office. (b) I prefer to visit the dental office. (c) I will wait until my next appointment.	50 (46.3) 24 (22.2) 34 (31.5)

(Table 1 Continued)

(Table 1 Continued)

(Table 1 Continued)

No.	Question	Options	Count (%)
Q9	Do you think the missed appointments will have an effect on your orthodontic treatment during the COVID-19 pandemic?	(a) It will prolong my overall treatment.	65 (60.2)
		(b) It will affect my treatment outcome.	20 (18.5)
		(c) It will not prolong my overall treatment.	7 (6.5)
		(d) It will not affect the treatment outcome.	16 (14.8)
Q10.	Would you like to undergo additional treatment procedures, if indicated by your orthodontist, to compensate for the lost time?	(a) Definitely	50 (46.3)
		(b) Probably	31 (28.7)
		(c) Possibly	18 (16.7)
		(d) Probably not	5 (4.6)
		(e) Definitely not	4 (3.7)
Q11.	Does your current financial situation have any effect on future orthodontic appointments?	(a) My financial situation is not affected, and I can afford further treatment.	38 (35.2)
		(b) My financial situation is affected, but I can afford the treatment.	56 (51.9)
		(c) My financial situation is affected, and I cannot afford further treatment.	14 (13.0)
Q12.	Protective gear and equipment to counteract COVID-19 may increase future treatment costs. What is your opinion?	(a) I understand the situation, and I will bear the extra amount.	23 (21.3)
		(b) I understand the situation, but I cannot bear the amount.	41 (38.0)
		(c) I won't pay the additional amount, as it was not informed before the start of treatment.	14 (13.0)
		(d) I expect the dental institution/clinician/government/insurance companies to bear the extra amount.	30 (27.8)

The questionnaire consisted of 12 closed questions, which the researchers considered to be ideal. The questions cover the fundamental importance of knowledge and the understanding of adult patients about the COVID-19 pandemic, and the financial burden and its impact on ongoing fixed orthodontic treatment. It was mandatory for the patients to answer all 12 questions to send their response. The Likert's response format was used for 7 questions, and the other questions were provided with options that are considered appropriate by the researchers. The initial questionnaire was rated by 6 experts involved in the provision of orthodontic care, and the item-level content validity index was 0.94. Minor changes in the questionnaire were made based on the suggestions received by the experts to make it more readily understandable to the subjects. The Cronbach's alpha of 0.86 demonstrated good internal-consistency reliability of the questionnaire when administered to 30 subjects meeting the inclusion criteria for this study. The questionnaire was also assessed for test-retest reliability through administering it to the same set of participants based on the response of whom Cronbach's alpha was derived. The intraclass correlation coefficient (ICC) of 0.91 between the test and retest responses was indicative of the temporal stability of the questionnaire. The typical time taken for completion of consent and the questionnaire was approximately 5 to 10 minutes.

Questionnaire Distribution and Study Duration

The online questionnaire was posted to 153 adult patients undergoing orthodontic treatment, selected through the random sampling method at GSLDC, India, on May 18, 2020. Google Forms® was used as an online plotting source, and the questionnaire's link was sent via WhatsApp or email to the patients on the contact list in the GSLDC orthodontic database. Online consent was obtained from the participants. All the responses were anonymous and could not be traced by the researchers. This was done to eliminate bias that could arise if patients felt that their answers could influence any aspect of their subsequent treatment. The deadline for the final return of the questionnaire was set for May 23, 2020.

Data Analysis

Of the 153 adult patients undergoing fixed orthodontic treatment, 108 consented to participate in this study. The findings from the questionnaire were analyzed using SPSS Version 20.0 (SPSS Corporation, Chicago, IL).

Results

A total of 153 adult patients undergoing fixed orthodontic treatment were approached to complete the questionnaire, and 108 completed responses were returned. The responses to each question are illustrated in Table 1. The gender distribution

of the study subjects and the differences in responses to the study questions based on gender are illustrated in Tables 2 and 3, respectively.

Discussion

The knowledge, understanding ability, and financial standing of adult patients play an influential role in the progress of fixed orthodontic treatment during the COVID-19 pandemic. In the course of fixed appliance therapy, a higher intensity of pain and discomfort was often reported.⁶ Although it varies based on the age and pain threshold of patients, our questionnaire was confined to adults, as patients below 18 might experience problems with specific complex questions and their characteristics might affect the quality of the data.⁷ After the questionnaire link was sent, there were a total of 108 responses, at a response rate of 70.5%, which seems to be similar to other orthodontic-based questionnaire studies published.⁸ However, the response rate is difficult to compare in light of this new aspect of the COVID-19 pandemic.

During the period of lockdown, patients might be in a state of stressful agony. This factor may well account for the missing responses and have resulted in some degree of pessimism.

Each Question Was Discussed to Benefit the Reader

- *Question 1: Are you aware that the COVID-19 virus spreads easily in the dental setup?*
Of the patients, 17.5% are slightly aware and 22.3% are not at all aware that the COVID-19 virus spreads quickly in a dental setup. Hence, there is still a need to educate and create awareness among patients regarding the COVID-19 pandemic irrespective of gender.
- *Question 2: Are you willing to undergo treatment from an orthodontic team who were previously affected with COVID-19?*
Of the patients, 5.6% are probably not willing to undergo treatment from an orthodontic team previously affected by COVID-19. Most patients believe that they

Notes: Questions 1, 3, 4, 5, 6, 9, 10 and 11 used Fisher's exact test. Questions 2, 7, 8 and 12 used the chi-square test. Q1 to Q12 are the questions asked, and (a) to (e) are the options provided (see Table 1). P ≤ .05 is considered statistically significant. * Denotes statistical significance.

could get infected via dentists with viral infections.⁹ Moreover, recurrence of COVID-19, with a previously infected person capable of transmitting the virus to other people even after a second negative test, has been reported in the literature.¹⁰ This could be a probable reason why patients tend to avoid treatment from a previously infected orthodontist.

- *Question 3: Are you willing to disclose your COVID-19 status and undergo pretreatment screening before every appointment?*

Of the patients, 64.8% are definitely willing, and the rest are still in a dilemma over disclosing their COVID-19 status and undergoing pretreatment screening before every appointment. This is a dangerous sign and might put many at risk of contracting the virus. Thus, we need to make patients understand the importance of their status disclosure and participation in a pretreatment triage.³

- *Question 4: What is your view on visiting the orthodontic office after the COVID-19 pandemic?*

Of the patients, 63.0% are willing to visit the orthodontic office after the COVID-19 pandemic if proper infection control precautions are followed. However, the rest of the patients fear cross infection in a dental office and do not want to risk it.⁹

- *Question 5: Do you adhere to strict appointment timings for the clinical area's adequate sanitization to counteract COVID-19?*

Of the patients, 71.3% are definitely ready to adhere to strict appointment timings to sanitize the clinical area to counteract COVID-19. More emphasis should be placed on this aspect among orthodontic patients. Additional time is required for proper sanitization of the clinical area, as the virus has been detected on stainless steel, on plastic, and in aerosols for up to 5.6, 6.8, and 3 hours, respectively.^{1,11}

- *Question 6: Would you like to adhere to "Strictly no accompanying person" (until and unless specified by the orthodontist) for future appointments?*

Of the patients, 53.7% would like to adhere to "Strictly no accompanying person" (until and unless specified by the orthodontist) for future appointments. The current unprecedented circumstances put the accompanying person also at risk of COVID-19 infection. Performing pretreatment triages as a routine procedure for accompanying persons adds a physical burden on the dental team.¹

- *Question 7: Do you have any pain or discomfort due to missed appointments during the COVID-19 pandemic?*

Of the patients, 34.3% have no pain or discomfort due to missed appointments during the COVID-19 pandemic. There is a nonlinear relationship between age, gender, psychological state, and cultural background in pain perception following placement of an orthodontic appliance, according to the literature. However, with

fixed orthodontic treatment, mild to moderate pain or discomfort is often experienced by patients.⁶

- *Question 8: For unexpected orthodontic problems, which of the following options do you choose?*

Of the patients, 46.3% preferred telecommunication in case of unexpected orthodontic problems. Gender distinction was observed in the participants' responses ($P = .06$). While most females expressed interest in teleconsultation with the dental office, males demonstrated readiness in visiting the dental office and seeking care. Teledentistry facilities should be encouraged during this pandemic to prevent unnecessary visits to the dental office. This would aid patients in resolving a new orthodontic problem that can be managed at home and help determine which patients need in-person attendance.

- *Question 9: Do you think missed appointments will have an effect on your orthodontic treatment during the COVID-19 pandemic?*

Of the patients, 60.2% think missed appointments due to the COVID-19 pandemic would prolong their overall treatment time. Association of the pandemic with orthodontic treatment time and outcome has not been previously investigated.

- *Question 10: Would you like to undergo additional treatment procedures, if indicated by your orthodontist, to compensate for the lost time?*

Of the patients, 46.3% are definitely willing to undergo additional treatment procedures to make up for the lost time. From a patient's perspective, shorter treatment times impact psychosocial well-being, which contributes to the overall quality of life.^{12,13} Comprehensive orthodontic treatment requires, on average, less than 2 years to be complete.¹⁴ The lost time during the pandemic prolongs the overall treatment duration. Males ($P = .022$) and more qualified participants ($P = .028$) expressed willingness to undergo additional procedures in this regard. However, the type of intervention and financial aspect may affect patients' decision to undergo additive procedures when indicated.

- *Question 11: Does your current financial situation have any effect on future orthodontic appointments?*

The virus has spread throughout the inhabited world and led to unprecedented financial crises. Of the patients, 51.9% opined that their financial situation is affected but they can afford future treatment. However, economic crises depend upon several factors, such as the lockdown period, type of occupation, and socioeconomic status.

- *Question 12: Protective gear and equipment to counteract COVID-19 may increase future treatment costs. What is your opinion?*

Of the patients, 38.0% revealed that while protective gear and equipment might increase future treatment costs, they cannot bear that extra amount, and 27.8%

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

expect the dental institution/clinician/government/insurance companies to bear the additional amount.

Limitations

A potential concern in this study is the noninclusion of the study participants' socioeconomic background and geographical location as independent study variables.

Though these parameters were documented at the beginning of the orthodontic treatment, they were not included in the present study's data analysis. A review of patient records suggests little variability concerning these parameters among the study subjects, who share the common characteristics of availing orthodontic treatment at a single facility at substantially lower costs because the facility is provided at a dental teaching institution. However, it would be interesting to see if the study results are replicated in geographical areas where COVID-19 is comparatively more prevalent.

The preliminary nature of the study with a small sample is a limitation.

The present study intended to qualitatively explore patients' attitudes regarding ongoing orthodontic treatment during challenging COVID-19 times. Moreover, the study attempted to include all the eligible study subjects seeking care at the facility, as mentioned earlier, circumventing sampling. The authors opine that the observations made in this study form a concrete basis for future research to more thoroughly understand the attitudes, knowledge, and impact of COVID-19 on patients undergoing orthodontic treatment considering the study's preliminary nature with a small sample.

Conclusions

- Knowledge of cross infection, the importance of status disclosure, and pretreatment screening regarding COVID-19 was not up to mark for adult orthodontic patients.
- The understanding of the adult orthodontic patients regarding the significance of adhering to strict appointment timings and having no person accompany them to the orthodontic office during the COVID-19 pandemic was satisfactory.
- In the case of an unexpected orthodontic problem, most patients preferred telecommunication during this pandemic.
- Most patients think missed appointments due to the COVID-19 pandemic would prolong their overall treatment time, and the majority of them showed a willingness to undergo additional treatment procedures to make up for the lost time.
- The adult orthodontic patients mostly opined that there has been an impact on their financial situation due to

the lockdown but they can afford future treatment. A few cannot bear the extra amount due to protective gear and equipment, and patients expect the dental institution/clinician/government/insurance companies to cover this.

Declaration of Conflicting Interests

The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Saliva as a Reliable Diagnostic Tool during the Coronavirus Disease Times: A Focused Review

Sarita Shaukari, Souren Bellam¹, K. Raghu Nandan², Revathi Peddu

Department of Orthodontics, SIBAR Institute of Dental Sciences, ¹NRI Academy of Medical Sciences, Guntur, Andhra Pradesh, ²Department of Oral and Maxillofacial Surgeon, Bharathi's Ora Care, Yelahanka, Bangalore, India

Abstract

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), also currently known as CoV disease 2019 (COVID-19), has created a global health upheaval. The saliva of an infected person serves as a source for the transmission of CoV. The angiotensin-converting enzyme-2 receptors serve as the host receptor cells for CoV which is expressed in high numbers in salivary glands, oral mucosa, and gingiva. The salivary gland is a potential reservoir for COVID-19 even in asymptomatic but infected carriers. This knowledge could be used to employ salivary sampling as a noninvasive diagnostic method. IgA, IgM antibodies detected in self-collected saliva show more stability than RNA and may aid in the identification of asymptomatic patients. Saliva shows high sensitivity and specificity in the diagnosis of COVID-19 with >90% concordance reported between the saliva and nasopharyngeal swabs. Standardization with respect to sample collection, storage, and transport media can help in validation of diagnostic application of salivary-based testing.

Keywords: Corona virus, reverse transcription-polymerase chain reaction, saliva and coronavirus disease-2019, salivary diagnostics, severe acute respiratory syndrome coronavirus 2

Submitted: 08-Dec-2020; **Revised:** 19-Dec-2020; **Accepted:** 20-Jan-2021; **Published:** 08-Oct-2021

INTRODUCTION AND BACKGROUND

Declared as a pandemic by the WHO on March 11, 2020, Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), also currently known as CoV disease-2019, (COVID-19) has created a global health upheaval.^[1]

The last two decades have witnessed three major global health issues, namely the SARS CoV, Middle East Respiratory Syndrome (MERS) CoV, and the SARS-CoV-2, with a mortality rate of 9.5%, 34.4%, and 2.3%, respectively. Although COVID-19 expresses a much lower mortality rate, it has raised alarm with its capability to spread much more rapidly than MERS-CoV and SARS-CoV.^[2]

TRANSMISSION

Majorly, COVID-19 transmission occurs through the direct and indirect modes. Direct mode of transmission occurs through respiratory droplet nuclei generated by an infected person while talking, coughing, sneezing, and through aerosols generated during the clinical procedures. Body fluids and discharges, for example, feces, saliva, urine, semen, and tears also serve

as a potential transmission route. The exposure and risk of transmission is elevated if the infected person is present within 1 m radius of a susceptible host. Indirect transmission may occur through fomites or through surfaces, objects that have come in contact with the infected.^[3]

TESTS FOR DETECTING CORONAVIRUS DISEASE-2019

Most of the tests used for Covid-19 detection can be grouped under the polymerase chain reaction (PCR) or serological tests. All these necessitate sample collection employing various means to identify the characteristic hallmarks of the SARS-CoV-2 virus.^[4]

Although chest computed tomography scans sound promising with high sensitivity for COVID-19 detection, they cannot be employed for mass screening due to low specificity, huge

machinery involved, difficulty in sterilization as well as increased radiation exposure.^[5]

Reverse transcription-PCR is being considered as the gold standard for the detection of novel CoV.^[6] However, this requires the need for nasopharyngeal swabbing by skilled medical personnel. In addition, it is known to be less tolerant to patients. Literature documents it to be contraindicated in patients with significant nasal septum deviation, recent facial trauma, patients on anti-coagulant therapy and thrombocytopenic patients; in whom bleeding can be anticipated. Furthermore, nasopharyngeal swabs are not considered to be suitable for serial controlling of viral load.^[6]

All these limitations clearly picturize the need for a simpler sample collection technique which is not only less invasive but with minimal logistic burden.^[7,8]

SALIVA AND ITS POTENTIAL ROLE IN CORONAVIRUS DISEASE-2019 DIAGNOSIS

Sputum is a noninvasive lower respiratory tract specimen which has immense diagnostic value in diseases such as tuberculosis and chronic obstructive pulmonary disease, but Huang *et al.*^[9] in their study stated that only 28% of patients with 2019-nCoV can produce sputum. It also represents a drawback that it is mandatory to collect sputum only before tooth brushing and breakfast, as nasopharyngeal secretions move posteriorly, and bronchopulmonary secretions move by ciliary activity to the posterior oropharyngeal area, whereas the patients are in a supine position during sleep.^[10] Hence, these limitations eliminate sputum as a reliable diagnostic aid in COVID-19.

Few others have suggested the employment of blood specimens for rapid PCR-based assays or immunochromatography-based *in vitro* assays to detect specific antibodies. Although these techniques sound promising in terms of time, their suitability for screening at the large scale is questioned by procurement of blood samples at a medical point-of-care.^[10]

The saliva of an infected person serves as a source for CoV^[3,6] and this knowledge could be further investigated to determine if a noninvasive salivary diagnostic method could be employed for the COVID-19 detection for limiting the spread.^[11]

Asymptomatic patients provide a major challenge in the current diagnosis protocols of many countries. In a study by Azzi *et al.*,^[10] two patients who were monitored showed positive salivary results on the same days that their pharyngeal or bronchoalveolar swabs were negative. This raises the possibility that individuals can be contagious through their saliva even when pharyngeal swabs are negative. This could be a point in favor of employing saliva for virus detection and also further strengthens the view that salivary glands serve as potential reservoir for Covid-19 virus in asymptomatic but infected people.

Diagnostic strategies with high specificity and sensitivity for both asymptomatic and symptomatic potential “super

spreaders” may help combat against this cataclysmic pandemic.^[12]

Different pathways have been put forward to substantiate the presence of COVID-19 in saliva: First, it might be present in the liquid droplets constantly being exchanged in the upper and lower respiratory tract that enters the oral cavity. Second, virus in the blood can reach the oral niche through crevicular fluid. A study of SARS CoV in Rhesus macaques widely documented the susceptibility of epithelial linings of the salivary glands to infection. From the same, it might be suggested that infections of the minor, major salivary glands, and its ducts can serve as an entry portal for COVID-19. Drainage of debris from nasopharyngeal epithelium into the oral cavity serves as another potential route.^[8,11]

Xu *et al.*^[13] have demonstrated that the receptor-binding domain of SARS-CoV-2 spike protein supports strong interactions with the human angiotensin-converting enzyme-2 (ACE-2) receptor seen in taste cells, which might be responsible for infection-related ageusia. ACE-2 protein is also expressed in vascular endothelial cells, alveolar epithelial cells of lungs, enterocytes of the intestine, and myocardial cells. Hence, justifying the higher susceptibility of these organs to get infected by SARS-CoV-2.^[14] Appearance of ACE-2 is higher in minor salivary glands than that in the lungs.^[7] Among other oral sites, epithelial cells of the tongue exhibit the highest expression of ACE-2 followed by the buccal tissues and gingiva. Endothelial cells of the oral mucosa show exaggerated expression of ACE-2 during SARS-CoV-2 infection and may be responsible for the high viral load in saliva.^[15]

Brann *et al.*^[16] interpreted that the COVID-19 virus has damaging effects on nonneuronal olfactory epithelium causing anosmia, and its intimate correlation to the chemosensory senses of taste may be responsible for the resultant ageusia.

Investigations have further confirmed that SARS-CoV RNA is present in the saliva before the emergence of lesions in the lung. The positive rate of COVID-19 in salivary samples can exceed about 92%, and live virus can also be cultivated through the salivary samples.^[7] Whereas certain scenarios have required repeated nasopharyngeal swab sampling before a positive finding has been obtained in otherwise overt COVID-19 patients, suggestive of its compromised reliability.^[10] Many authors have substantiated the promising role of saliva in COVID-19 detection with high sensitivity, specificity, and consistency^[10,15]. More than 90% concordance has been displayed between self-collected saliva and nasopharyngeal swabs collected by health-care workers.^[15]

Various methods have been mentioned in the literature to collect saliva. A simple drooling technique has been suggested by Azzi *et al.*^[10] to collect saliva and the collected specimen was suspended in 2 ml of phosphate-buffered saline. To *et al.*^[17] collected saliva by coughing up and clearing the throat such that the collected sample contained fluid from the posterior oropharynx also. Williams *et al.*^[18] suggested a method in

which prior to collection, patients were asked to pool saliva and then spit 1–2 ml into a collection tube. However, this method of saliva pooling in the mouth might lead to dilution of the viral load in the specimen because of excessive saliva secretion.

TIMING OF SAMPLING

The fact that saliva may depict alteration due to physiological processes taking place throughout the day must be taken into consideration. Most of studies have requested participants to avoid oral stimulation such as eating, drinking, and oral hygiene practices during a certain period before a sample is taken therefore establishing standard sample conditions due to the presence of circadian rhythms in saliva and their effect on its composition.^[8,19]

It is recommended to collect saliva between 8 and 10 a. m. to reduce the influence of circadian rhythms on the results.^[19] Tajima *et al.*^[20] also found that early morning saliva specimens were more likely to show positive 2019-nCoV RNA results than daytime saliva specimens. The positive rate of saliva specimens collected during the early phase of onset defined as within 9 days of symptom onset was 93.4% and 63.0% after 10 days of symptoms.^[20,21]

PROSPECT OF SALIVARY BIOMARKERS IN CORONAVIRUS DISEASE-2019 PROGNOSIS

Coronaviruses delays or decreases interferon (INF) production which activates inflammatory responses triggering severe pulmonary conditions.^[22,23] The unregulated host immunological response and the “cytokine storm” are considered to correlate with poor prognosis and severity of the disease.^[22]

Recent studies have outlined that severity of COVID-19 cases can be correlated with elevated levels of granulocyte colony-stimulating factor, interleukin (IL)-2, IL-6, IL-7, IL-10, INF- γ -inducible protein-10, macrophage inflammatory protein-1A, tumor necrosis factor- α , and macrophage chemotactic protein, suggestive of inflammatory response mediated by cytokine release having a pivotal role in COVID-19 progression.^[9,23]

Saliva provides an opportunity to measure the markers of the inflammatory process such as chemokines and cytokines. Thus, evaluation of inflammation-related biomarkers in saliva can provide us with a platform to establish inflammatory profile assisting in prognosis stratification of COVID-19-infected patient.^[24]

ANTIBODIES AGAINST SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS 2

Supplementary to RT-PCR-based RNA detection of COVID-19, few have documented encouraging results for the detection of IgG and IgM antibodies in the serum/plasma samples of infected patients. Further investigations suggest it may be

justified to hypothesize that human saliva is a source for anti-SARS-CoV-2 antibodies.^[24]

Antibodies such as IgA and IgM have been detected in different biological fluids including self-collected saliva. These being more stable than RNA simplify the sampling process and aid in the identification of asymptomatic patients. Antibody detection tests also assist to track down how competitively the patient’s immune system is fighting against the virus and are potential guide for plasma transfusion therapies.^[24,25]

RUCDR Infinite Biologics at Rutgers University have stated that salivary testing equals in performance to the approved swab-based collection technique.^[26]

The salivary diagnostic technique offers us with an additional advantage of:^[27]

- Real-time diagnostic value
- Any number of samples can be easily collected
- Eliminates the need for specific clinical setup for the collection and screening of samples
- Unlike blood, saliva does not clot
- In comparison to serum, saliva requires less manipulation during the diagnostic procedures.

CONCLUSION

Salivary sampling for COVID-19 detection ensures high sensitivity, efficacy, reliability specificity, and concordance. Saliva offers a promising diagnostic alternative and can minimize the risk of nosocomial transmission. The current article highlights the pivotal role of saliva in COVID-19 detection.

Scope for future research

Insight into diagnostic application of saliva for COVID-19 detection brings with it a strong promise, at the same times opens up immense scope for investigation with regard to optimal temperature for sample collection, storage, and ideal transport media. Standardization of an appropriate assay can help in validation for the diagnostic application of saliva. The reliability of gingival crevicular fluid as a diagnostic source for COVID detection also needs further insight.

Occlusal stress distribution in the human skull with permanent maxillary first molar extraction: A 3-dimensional finite element study

Safiya Sana, Rony T. Kondody, Ashok Kumar Talapaneni, Asma Fatima, and Sayeeda Laeque Bangi
Gulbarga, Karnataka, India

Introduction: The objective of this research was to analyze the effect of orthodontic treatment with maxillary permanent first molar extraction on the occlusal stress distribution and displacement in the human skull. **Methods:** A 3-dimensional finite element model was constructed on the basis of a computed tomography scan, and it was used as the pretreatment model. The software used for geometric modeling was Solid Works (Dassault Systèmes, Paris, France). For the extraction model, the maxillary permanent first molar was removed, followed by a repositioning of the anterior and posterior segments to create a space closure model. Stress distribution was evaluated under the simulation of 1000 N for occlusal forces and 400 N for masseter muscle force. **Results:** The highest von Mises stress was observed at the zygomatic process of the temporal bone across all 3 models (25 MPa), whereas stress at the pterygomaxillary suture area was almost 50% less. However, the stress in the pterygomaxillary suture area was lowest in the extraction model (18%) and space closure (30%). Stress in the zygomatic process of the frontal bone and frontal process of the maxilla increased from pretreatment to extraction model followed by space closure model. **Conclusions:** The occlusal forces were transferred through maxillonasal, maxillozygomatic, and maxillopterygoid stress trajectories. The mesial displacement of the molars may weaken the role of maxillopterygoid stress trajectory while strengthening the role of maxillonasal stress trajectory. (Am J Orthod Dentofacial Orthop 2021; ■: ■-■)

The occlusal forces during mastication are transferred through the teeth, periodontal ligaments (PDLs), and the alveolar bone to the supporting structures of the skull.¹ Theoretical fundamentals of biomechanics explain the skull architecture on the basis of bone pillars in the maxilla and trajectories of stress dissipations in the mandible.²

According to Sicher,³ the masticatory forces are dissipated from the alveolar process to the 3 enhanced bone pillars in the maxilla, located at each antimer and bypassed by nasal and orbital cavities. The canine and zygomatic pillars (ZPs) are horizontally connected along

with the supra and infraorbital edges, which act as beams that resist the mechanical stresses. The pterygoid pillar is an enhanced bone arched toward the skull base and hard palate, connecting the pillar systems on each side of the skull.² The nature of strain and stress distribution helps in better understanding of diagnosis and treatment of stomatognathic diseases and reconstruction of masticatory function.⁴

It is generally accepted that the maximal occlusal force is higher in molars than incisors.⁵ There is an inherent relationship between key ridge, infrazygomatic crest, and the position of the first molar.⁶

Recent dental health surveys in the United Kingdom have shown an increase in the incidence of decay associated with the first molar, and it also significantly display enamel hypoplasia.^{7,8} As a general rule, the compensating extraction of a maxillary first permanent molar has been recommended when extraction of the mandibular first permanent molar is required. This is to avoid supraeruption of an unopposed maxillary first permanent molar, which can prevent desirable mesial movement associated with the erupting mandibular

second permanent molar and other occlusal interferences, whereas balancing extraction of sound first permanent molar has been recommended to preserve arch symmetry.^{9,10}

In certain occlusions, when space is not required to reduce overjet or relieve crowding, it may be beneficial to extract the first molar, which favors mesial eruption of the second molar into extraction space.¹¹

In the finite element study by Cattaneo et al,¹² the forward and backward displacements of the maxillary molars from the infrazygomatic crest affected the pattern of load transfer through the maxillary complex. Thus, it becomes important to determine the areas of stress distribution in patients with missing or extracted maxillary first molars.

The finite element analysis (FEA) is the most advanced and precise tool in biomechanical research. It is the ultimate method for modeling complex structures and analyzing their mechanical properties.¹³ It allows establishing the location, magnitude, and direction of an applied force, as it may also assign stress points that can be theoretically measured. Furthermore, it does not affect the physical properties of the analyzed materials.¹⁴

However, to date, there have been no studies dealing with the stress distribution and displacement after orthodontic treatment with maxillary first permanent molar extraction. The purpose of this study is to evaluate and analyze the effect of orthodontic treatment with maxillary permanent first molar extraction on the occlusal stress distribution in the skull by FEA.

MATERIAL AND METHODS

A 3-dimensional (3D) FEA model of a human skull was produced on the basis of computed tomography (CT) scan data of a healthy 15-year-old male patient with no craniofacial anomaly. The CT scan was taken for study with a 3-mm scan increment and a 1-mm slice thickness. The model had a set of all permanent dentition with normally erupted teeth and maxillary permanent first molar with a poor prognosis on the right side. The protocols of this study were approved by the ethics committee of the institute (IEC/2017-18/02). The CT scan was read into image processing software (Mimics, version 14.0; Materialise, Leuven, Belgium). The images were segmented by thresholding to obtain the right skull and maxillary teeth. The 3D reconstruction of these parts was then formed with a surface triangularization technique (Fig 1). This reconstruction formed the basis for the so-called pretreatment model. The triangularized shapes of the bone were subsequently read into image processing software to manipulate the molar position. The 3D models were assumed to have maxillary teeth, PDLs (0.25-mm thick),¹⁵ and cortical and cancellous bone thickness of 1-mm thick.¹⁶ CT scan images of the maxilla, including the skull, are made with a top cutting plane. The physical model of brackets was scanned at Advance CAD Technologies Pvt Ltd (Pune, India), using REXCAN III 3D white light scanner (Solutionix, Seoul, South Korea). The computer-aided designing model with proper details about the brackets and teeth were obtained. The obtained computer-aided designing model was used to construct the geometric model of the teeth with the bonded brackets in Geomagic Design X software (3D Systems Manufacturing, Rock Hill, SC).

The software used for geometric modeling and to import individual CT scan sections and traced was Solid Works (Dassault Systèmes, Paris, France). Individual CT scan sections were imported into the Solid Works software and traced, taking care not to disturb the anatomy of the region. These blocks were imported into HyperWorks software (version 13.0; Altair Engineering, Troy, Mich).

The study aimed to determine the occlusal stress distribution and displacement in the human skull after permanent maxillary first molar extraction. For the boundary conditions, the movement was restricted in the top cutting plane.

The von Mises stress and the normal stress were evaluated under the simulation of 1000 N for the occlusal force on the maxillary right teeth and the simulation of 400 N for the masseter muscle force, which originated at the inferior part of the zygomatic arch and inserted into the lateral surface of the ramus of the mandible, before and after extraction of maxillary permanent first molar¹ (Table I). To produce the extraction model, the permanent maxillary right first molar was removed. Then the anterior segment was repositioned back by 4.1 mm and the posterior segment forward by 6.9 mm on the sagittal plane (Fig 2). Buccolingual minor repositioning and rotation of the anterior and posterior dental segments were done to maintain the continuous curvature of the dental arch. The stress was compared at 4 points within the main stress trajectories: the frontal process of the maxilla (FM), the zygomatic process of the frontal bone (ZF), the zygomatic process of the temporal bone (ZT), and the pterygomaxillary suture area (PM).

The linear FEA method has been used, and all the materials were assumed to be isotropic, homogenous, and linearly elastic. The total number of nodes and elements in the pretreatment model were 207,148 and 1,072,185 for teeth, 98,532 and 145,986 for a PDL, 138,225 and 680,737 for alveolar bone and skull bone. In the case of the extraction model, a total number of nodes and elements were 167,902 and 869,724 for teeth, 92,654 and 134,864 for a PDL, 138,225 and 680,737 for alveolar bone and skull bone, 11,802 and 45,587 for the bracket, 2653 and 980 for archwire whereas in space closure model, 167,902 and 869,724 for teeth, 92,654 and 134,864 for a PDL, 147,231 and 694,632 for alveolar bone and skull bone. The space closure model had a higher number of nodes and elements than the other 2 models. After extraction of the first molar, as the second molar moved anteriorly, these geometric changes in the position of the second molars led to the reconstruction of the space closure model with highly refined mesh. The precision of the FEA calculation increases as

Table I. Loading conditions¹

Force application point	Model		
	Pretreatment	Extraction	Space closure
Central incisor	20	20	20
Lateral incisor	20	20	20
Canine	20	20	20
First premolar	60	120	120
Second premolar	60	140	140
First molar	370	–	–
Second molar	450	680	680
Total occlusal force	1000	1000	1000
Masseter muscle	400	400	400

Note. Values represent force (N).

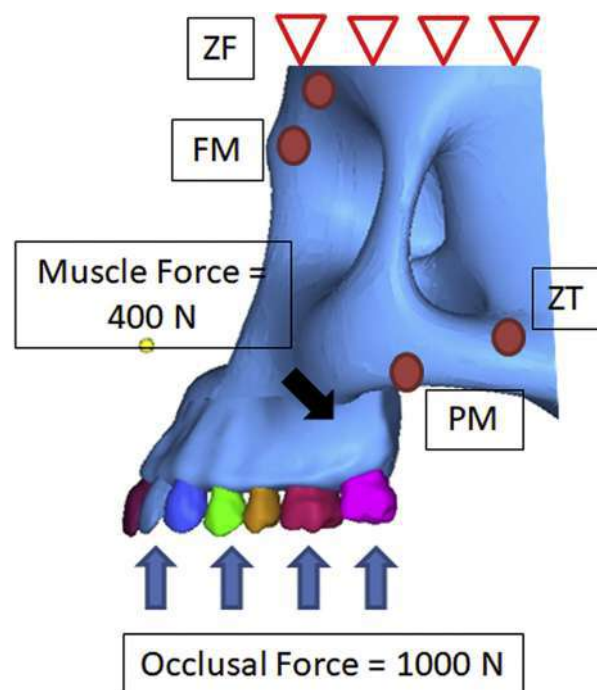

Fig 2. Lateral view of the FEA model. The boundary and external loading conditions are shown. The amounts of stress in both models were compared at 4 points: the FM, ZF, ZT, and PM.

highly refined meshes of the model are used. The highly refined mesh is required in critical areas such as areas with a higher stress concentration and zones of complex and highly curved geometric shapes within the model.⁴ Hence, a mesh convergence study was recommended. The space closure model was reanalyzed using a 10-noded tetrahedral element to ensure convergence in the pattern of stress; therefore, discretization error can be well controlled to get more accurate results with a reasonable model dimension. The material properties

of the bone and teeth in the model were defined according to experimental data from previous studies.^{1,17-19} (Table II).

RESULTS

When occlusal forces were applied to the maxillary dentition, the stresses were observed and distributed throughout the skull (ie, the PDL, alveolar bone, maxilla, zygomatic arch, and reached the frontal and temporal bones in all the 3 models). A high concentration of stresses was present at the zygomatic arch and infrazygomatic crest. The stresses were also concentrated in the pyriform aperture, infraorbital rim, and pterygoid plate areas.

The von Mises stress expresses the overall stress intensity, and its distribution gives an impression of overall load transfer. The von Mises stress was highest at ZT across all 3 models (25 MPa), whereas von Mises stress in PM (13.5 MPa) was almost 50% less than the stress at ZT. Stress in PM was reduced in the extraction model (11.36 MPa) by approximately 18%, whereas 30% reduction in von Mises stress was observed for the space closure model (10.24 MPa). The stress in ZF and FM increased from pretreatment (11.92 MPa and 20.17 MPa) to the extraction model (17.63 MPa and 22.35 MPa) and further in the space closure model (18.91 MPa and 24.82 MPa), respectively (Fig 3; Table III).

The normal stresses were distributed in the x-, y-, and z-axes. In the vertical direction (y-axis), compressive stresses were found at the infrazygomatic crest, PM and FM, whereas tensile stress was found at ZF (Fig 4; Table IV). The reversal of stresses (ie, compressive to tensile stress) was seen at ZT from pretreatment (0.56 MPa) to space closure model (0.16 MPa). The compressive stress at PM (1.03 MPa) was lower in the pretreatment model than the extraction model (1.23 MPa) and space closure model (1.16 MPa), whereas stress at FM was higher in the space closure model (0.21 MPa) than the pretreatment model (0.18 MPa) followed by extraction model (0.16 MPa).

In the anteroposterior direction (z-axis), compressive stresses were found at the zygomatic process of the frontal bone and the infrazygomatic area, whereas tensile stresses were found at the infraorbital rim, alveolar bones near the teeth, and the zygomatic process of the temporal bone in all the 3 models. The compressive stress was highest at PM in the pretreatment model (3.30 MPa), whereas it was slightly reduced in the extraction model (3.06 MPa), and in the space closure model, it was lowest (2.46 MPa). Tensile stress was highest in the pretreatment model (2.20 MPa)

Table II. Material property data representation^{1,17-19}

Material	Young's modulus (MPa)	Poisson's ratio
Teeth	20,000	0.3
Cortical bone	13,700	0.3
Trabecular bone	1370	0.3
Stainless steel archwire	200,000	0.3
PDL	0.13	0.45
Brackets	193,000	0.35
Buccal tube with traction arm	200,000	0.3

at ZT when compared with the extraction model (2.03 MPa) and space closure model (1.91 MPa) (Fig 4; Table IV).

In the lateral direction (x-axis), the compressive stress was found at the infrazygomatic area, frontal process of the maxilla and pterygomaxillary suture area, and the tensile stresses were found at the infraorbital rim and the alveolar bones near the teeth in all the 3 models. The highest compressive stress was seen at PM in the extraction model (6.01 MPa) when compared with its corresponding pretreatment model (5.67 MPa) and space closure model (4.82 MPa). In contrast, the lowest stress was seen at FM in the pretreatment model (0.35 MPa) when compared with the extraction model (0.36 MPa) and space closure model (0.42 MPa), whereas tensile stress was seen at ZT, in which the highest stress was in space closure model (0.78 MPa), and the lowest stress was in the pretreatment model (0.47 MPa) compared with the extraction model (0.53 MPa) (Fig 4; Table IV).

In the x-, y-, and z-axes, the space closure model showed a different stress pattern than the pretreatment model, and the compressive stress decreased at PM lateral (x-axis) and anteroposterior direction (z-axis). In addition, in the ZT area, the stress pattern was changed from compressive to tensile stress in a vertical direction (y-axis) (Fig 4; Table IV).

Maxillary displacement in the pretreatment and extracted model was the same (0.57 mm). However, a different displacement pattern was observed in the space closure model (0.55 mm). The pretreatment and extraction model had maximum displacement seen at the posterior segment with a v-shaped triangular pattern observed in the palatal region. However, the space closure model had different and exactly opposite v-shape triangular patterns that were seen in the palatal aspect (Fig 5; Table V). In the space closure model, the molar moves ahead by 70%, and the anterior segment moves behind by 30% of extraction space.

ZT	25.12	25.34	25.72
PM	13.45	11.36	10.24

Note. Values are presented as MPa.

DISCUSSION

Understanding the pattern of occlusal load distribution is very important as it not only reflects the functional morphology but also prevents bone damage caused by excess masticatory load and orthodontic forces.^{1,2} The pattern of occlusal force distribution observed in our study was consistent with the classical theory of buttresses (ie, the occlusal forces were transferred through the maxillonasal, maxillozygomatic, and maxillopterygoid buttresses), as previously reported.^{20,21}

The maxillary first molar is considered as the key to occlusion and has a favorable anatomic functional relationship with the zygomatic alveolar crest and ZP.² Previous studies by Cattaneo et al¹² and Gross et al²² confirmed that the first molar occlusal relationship could influence the stress distribution to the ZP, which had a significant impact on the success and failure of orthodontic treatment and anchorage implants.

Daugaard-Jensen,²³ suggested that patients with first molar extraction were no more time consuming than patients with 4 premolar extraction as it offers distinct advantages in terms of anchorage management, and this was supported by Williams and Hosila,²⁴ who highlighted the fact that extraction of the first molar will have less effect on the profile and a 90% chance

of successful third molar eruption compared with the approximately 55% chance with patients with premolar extractions.

The von Mises stresses were higher at the zygomaticotemporal suture and nasofrontal areas than at the pterygoid plate and zygomaticofrontal suture areas in all the 3 models, from which it can be inferred that these areas play an important role in bearing and transferring stress (Fig 3; Table III). The findings of the present study were in agreement with Hilloowala and Kanth,²⁵ who concluded that one of the most resistant areas of the skull involved in the distribution of stress of masticatory force is the ZP. However, in the extraction and space closure models, the von Mises stress decreased in the PM and increased in the ZF and FM, compared with the pretreatment model. Thus, the mesial displacement of the molars resulting from orthodontic treatment weakens the role of the maxillopterygoid stress trajectory (PM) while strengthening the role of the maxillonasal stress trajectory (FM). Furthermore, this study was in agreement with the study conducted by Choi et al,¹ in which after extraction of maxillary first premolar showed a similar pattern of stress distribution and concentration of stresses at the same trajectories.

In the vertical direction (y-axis), compressive stresses were found at the infrazygomatic crest, PM, and FM, whereas tensile stress was found at ZF (Fig 4; Table IV). Interestingly, we observed a reversal of stresses (ie, compressive to tensile stress) at ZT from pretreatment to space closure model. This reflects the equilibrium force (ie, compressive stresses created by the upward occlusal force and the tensile stress by the downward masseter muscle force), creating a balance in these areas. The stresses were moved more anteriorly, contributing to the bending of the zygomatic bone downward. Our finding was in agreement with studies by Choi et al,¹ Cattaneo et al,¹² and Prado et al.²⁶

NORMAL STRESS DISTRIBUTION

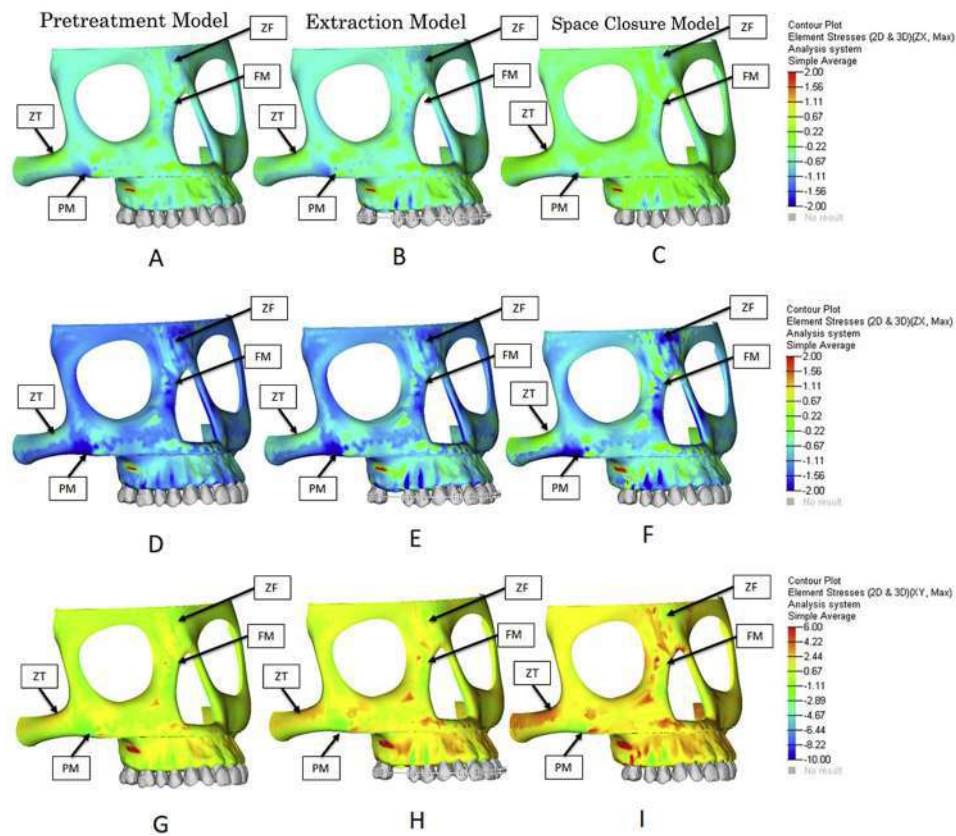

Fig 4. Normal stress distribution along the y-axis (A-C), z-axis (D-F), and x-axis (G-I). Blue color (negative value) represents compressive stress, whereas red color (positive value) represents tensile stress.

Table IV. Normal stresses in the pretreatment, extraction, and space closure models

Area	Models								
	Y-axis			Z-axis			X-axis		
	Pretreatment	Extraction	Space closure	Pretreatment	Extraction	Space closure	Pretreatment	Extraction	Space closure
FM	-0.18	-0.16	-0.21	-1.236	-3.299	-1.362	-0.35	-0.36	-0.42
ZF	0.65	0.62	0.63	-0.807	0.566	-0.390	-2.24	-2.03	-1.67
ZT	-0.56	-0.67	0.16	2.199	2.031	1.907	0.47	0.53	0.78
PM	-1.03	-1.23	-1.16	-3.299	-3.059	-2.462	-5.67	-6.01	-4.82

Note. Values are presented as MPa. Negative values indicate compressive stress, and positive values indicate tensile stress.

In the anteroposterior direction (z-axis), compressive stresses were found at the zygomaticofrontal bone and the infrazygomatic area, whereas tensile stresses were found at the infraorbital rim, alveolar bones near the teeth, and the zygomatic process of the temporal bone in all 3 models. In the pretreatment model, the compressive stress was highest at the PM area, whereas tensile stress was highest at ZT (Fig 4; Table IV). This was because the application of mechanical loading creates

a resultant to the masseter muscle contraction, which showed 2 lines of tensile stress at the maxillary sinus walls.

According to studies by Blaney²⁷ and Blanton and Biggs,²⁸ sinus walls are areas of compact bone located between the skull pillars, which were resistant to the masticatory forces. The low tensile stress on the floor and high tensile stress at the lateral wall confirm that resultant forces of the masseter muscle contraction

DISPLACEMENT

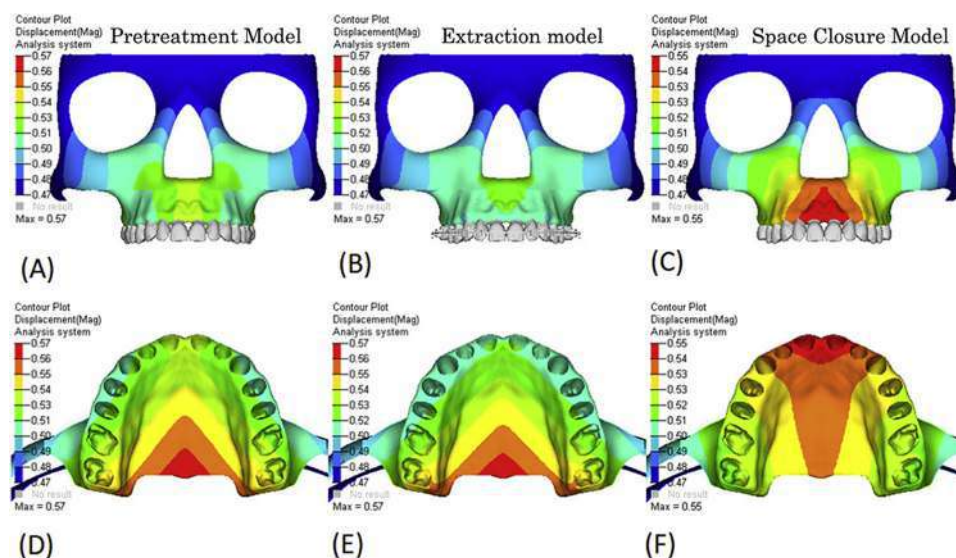

Fig 5. Displacement (frontal view - A-C and occlusal view - D-F) in the pretreatment, extraction, and space closure models. Red color indicates tensile stress (+) and Blue color indicates compressive stress (-).

Table V. Displacement in the pretreatment, extraction, and space closure models

Variable	Pretreatment model	Extraction model	Space closure model
Displacement	0.57 mm	0.57 mm	0.55 mm

were nonuniformly distributed through the ZP.² Tensile stresses were also observed in the alveolar bone near the teeth, and compressive stress was observed in the interdental area between the second premolar and second molars.

According to Frost,²⁹ when bone strains are below a lower threshold range, disuse-mode remodeling can turn on to reduce whole bone strength by removing some amount of trabecular and endocortical bone. If the alveolar bone does not adapt physiologically to the local change in the stress distribution in relation to the mesial displacement of maxillary second molars after extraction of the maxillary first permanent molar, alveolar dehiscences and fenestrations can occur in this area.^{1,12,29}

In the lateral direction (x-axis), the compressive stress was found at the infrazygomatic area, frontal process of the maxilla and pterygomaxillary suture area, and the tensile stresses were found at the infraorbital rim and the alveolar bones near the teeth and the zygomatic

process of the temporal bone in all the 3 models (Fig 4; Table IV). The highest compressive stress was seen at PM in the extraction model, and the lowest stresses were seen at FM in the pretreatment model, whereas the highest tensile stress was seen at ZT in the space closure model. It can be explained that as the occlusal force and masseter muscle force are not on the same line of force, the occlusal force does not disappear when the masseter muscle force appears.

From this stress pattern, it can be speculated that the entire maxillary complex may bend in the frontal plane and sagittal plane, resulting in the compression of the midpalatal suture area. This was in support of studies conducted by Burkes et al³⁰ and Jainkittivong and Langlais,³¹ who concluded that stresses cause the crestal alveolar bone to grow along the opposing vector of occlusal forces. Therefore, an altered function may lead to the development of exostosis in genetically predisposed populations.

Maxillary displacement in pretreatment and extracted models were the same. However, a different displacement pattern was observed in the space closure model. The pretreatment and extraction model had maximum displacement seen at the posterior segment with a v-shaped triangular pattern observed in the palatal region. However, the space closure model had different and exactly opposite v-shape triangular

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

patterns seen on the palatal aspect (Fig 5; Table V). From this finding, it can be assumed that this change in displacement pattern might be due to treatment resulting in strengthening nasomaxillary stress trajectories and an increase in cortical bone thickness in this region.

CONCLUSIONS

The present study derived the following conclusions:

1. The occlusal forces were transferred through the maxillonasal, maxillozygomatic, and maxillopterygoid stress trajectories
2. The mesial displacement of the molars resulting from orthodontic treatment may weaken the role of the maxillopterygoid stress trajectory (PM) while strengthening the role of the maxillonasal stress trajectory (FM)
3. Bone adapts physiologically to such local change in stress distribution; if not, dehiscences and fenestrations may occur.

3D Printing

Digital dentistry

ABSTRACT

The power, predictability and speed that today's digital solutions offer to human oral health care have gained a rapidly growing foothold in clinical dentistry. One such revolutionary innovation is the rapid prototyping technique. This technique facilitates the fabrication of physical models from computer aided design (CAD) data using 3D printers. This technique enables the dentist and laboratory technician to produce dental-related prosthesis with a greater speed and accuracy, thus making it a reliable alternative to the much labour intensive and time consuming hands on procedure. The present article reviews this current technology, its historical development, methods and applications in dentistry.

1. Introduction

The necessity of answering geometrical complexity has led to the introduction of Rapid Prototyping into the dental setup. It has the potential to become the next 'state-of-art fabrication technique in modern dentistry.¹ Rapid Prototyping equips us to broaden our vision in this era of digitalization, from conventional two-dimensional (2D) thinking to more informative three-dimensional (3D) thinking.²

Rapid Prototyping (RP) enables quick and automatic construction of a three-dimensional (3D) model of a part/product utilizing stereolithography machines or 3D printers.¹ Initially, slicing of digital models is done, then through automated layer-by-layer construction, transverse sections are produced and these 3D physical structures are known as rapid prototypes.³

RP is also termed as Layered manufacturing, Solid freeform fabrication, or Generative manufacturing.⁴

Digitalization in the form of Rapid Prototyping not only provides a brilliant break-through in various aspects of dentistry like orthodontics, prosthodontics, oral surgery, implantology and operative dentistry etc, but it also has created a great spur on the current time consumed on traditional laboratory design and procedures.²

The pivotal objective of this review is to focus on the types of Rapid Prototyping technique and its applications in the field of dentistry.

It provides fascinating opportunities in various aspects of dentistry like orthodontics, prosthodontics, oral surgery, implantology and operative dentistry etc. The key objective of this review is to focus on recent advancements of RP technology and its applications in dentistry.

2. Timeline

The concept of RP is not new and has seen development at various timelines.^{5,6}

- 1894 - Chuck Hull first introduced the concept of 3DP described it as stereolithography (SLA).

* Corresponding author.

2. 1957 - World's first CAM software program using a numerical control programming tool named PRONTO by Dr Patrick J. Hanratty.
3. 1971 - Computer-assisted production of dental restorations by Duret.
4. 1988 - Hull and the company 3D system developed the first 3D printer termed "SLA apparatus".
5. 1990 - Scott Crump engineered a technique called "FDM".
6. 1992 - Introduction of SLS.

3. Steps in RP Models Production

Rapid prototyping involves fabrication of a 3-D physical model directly from a computer-aided design model. Either contact or non-contact technique can do data acquisition.⁷ They all start with a 3D computer-aided design (CAD) model of the anatomical area, which usually can be derived from X-ray CT or MRI data.⁷ The steps involved in RP model production are summarised in Table I. Steps have been represented in Figure 1.

Table 1: Steps in RP models production

CAD-CAM steps	CAD-CAM system
Data acquisition	Contact or non-contact methods Example: Optical modeling, laser scanning, CT, MRI, digital photographs
Data processing	Digital data is processed to obtain a CAD model
Model fabrication	Rapid prototyping, CNC milling

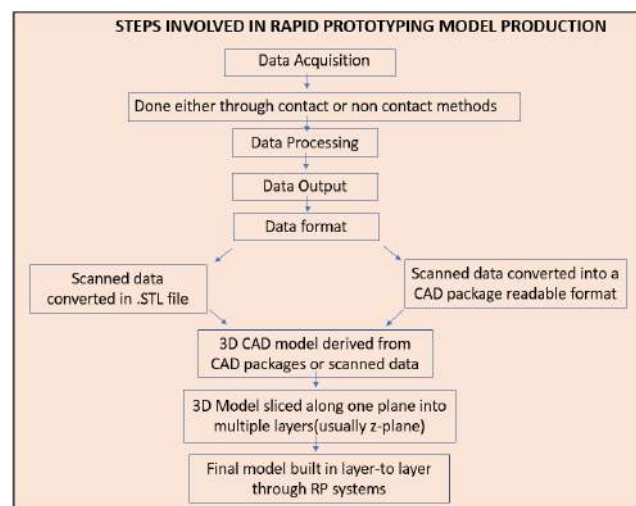

Fig. 1: Schematic flowchart of steps involved in RP model production

4. Digital Approaches for a Physical Prototype

The emergence of advanced digital technology has opened new perspectives in clinical dentistry.⁸ To fabricate a

physical prototype or a scale model through digital technology, two different approaches can be used:

1. Subtractive approach.
2. Additive approach.

Subtractive approach is usually facilitated using computer numerical control machining (CNC milling). The data principally obtained from an optical or contact probe surface digitizer captures the external surface data of the prescribed anatomy and not the internal tissue surface, hence less effective. This approach relies on milling an available larger blank using a CNC machine.⁹ The CAM software automatically translates the designed CAD model into a tool path for the CNC machine. This involves series of procedures, including sequencing, milling tools, and tool motion direction and magnitude. The dental CNC machines are composed of multi-axis milling devices facilitating 3D milling of dental prosthesis.

4.1. 3-axis milling devices

These are the most commonly used. The milling burs move in three axes (x -, y - and z - axes) according to calculated path values. Therefore, 3-axis milling has the advantage of having minimal calculation and cumulative milling time.⁹

4.2. 4-axis milling devices

These machines allow for blank movements in an additional axis, which helps mill a larger blank producing long-span frameworks.⁹

4.3. 5-axis milling devices

The 5th axis in this machine provides a rotating path of the milling tool or the blank. This facilitates the production of very complex geometries and smooth external surfaces such as acrylic denture bases.⁹

Keynote: For dental applications, the quality of the restoration is independent of the number of axes; instead, it reflects the method of processing the workpieces and CAD path of milling.

The Additive approach, on the other hand, can produce arbitrarily complex shapes with cavities such as human anatomical structures with the use of rapid prototyping. Additive manufacturing is defined as joining materials to make objects from 3D model data, usually layer upon layer. Once the CAD design is finalized, it is segmented into multislice images. The machine lays down 5–20 layers for each millimeter of material successively with liquid and powder that fuses to create the final shape. This is followed by workpiece refinement to remove the excess materials and supporting arms.¹⁰

4.4. Types of Rapid Prototyping Techniques:

Rapid Prototyping system commonly engaged in dentistry are:

1. Stereolithography (SLA),
2. Inkjet-based system (3D printing - 3DP),
3. Selective laser sintering (SLS and selective laser melting),
4. Fused deposition modeling (FDM).

Keynote: All the methods share the common work principle that distinguishes them from subtractive manufacturing:

1. Incremental vertical object build-up
2. No material wastage
3. Production of large objects
4. No application of force (passive production)
5. Production of fine details

4.5. Materials used for rapid prototyping

Wax, Plastics, Resins, Ceramics and Metals in the form of powder and liquid, Modeling materials and colors, such as medical-grade ABS, polycarbonates.⁵

4.6. Stereolithography

It creates a three-dimensional model using a computer-controlled moving laser beam to build up the required model from a liquid in a layer-by-layer manner. The first process of this type of RP was patented by Hull (1984).

4.7. Components of this system

A bath of photosensitive liquid resin, a model-building platform, and an ultraviolet (UV) laser for curing the resin.

4.8. Procedure

On the model-building platform, a layer of resin is exposed to UV light. After a resin layer is cured and hardened, the cured resin platform is lowered to the bath by a pre-fixed distance. A Wiper blade is used to wipe a new layer of resin across the previous layer, which is consequently exposed to the UV light and cured. The process of curing and lowering the platform into the resin bath is repeated until the complete model is built. (Figure 2)⁴ The self-adhesive property of the material causes the layers to bond to each other and eventually form a 3D object. The model is then removed from the bath and for then placed in a UV cabinet for sometime.^{11,12} The advantages and disadvantages of this technique are described in Table 2.

5. Inkjet-Based System (3D printing - 3DP)

A measured quantity of powder is dispensed from a supply chamber by incremental upward movement of piston. The

Table 2: Stereolithography

Advantages	Disadvantages
High accuracy	Expensive equipment
Good surface finish	High Material cost
Can be made transparent	Can be used only for polymers
100 percent density possible	Requirement of Post - cure
High-mechanical strength	
Fine building detail	

Fig. 2: Schematic diagram of stereolithography

roller then distributes and compresses the powder at the top of the fabrication chamber. Then a multi-channel jetting head subsequently deposits a liquid adhesive in a 2D pattern onto the layer of the powder, which becomes bonded in the areas where the adhesive is deposited to form a layer of the object. Once a layer is finished, the piston that supports the powder bed and the part lowers so that the next powder layer can be spread and selectively joined. This layer-by-layer technique is gradually continued until the prototype is completely built up. (Figure 3)⁴ The unbound powder is swept off with a heat treatment process, leaving the fabricated part intact.¹³ The advantages and disadvantages of this technique are described in Table 3.

Table 3: Inkjet based system

Advantages	Disadvantages
Fast fabrication time	Large tolerance
Low material cost	Lower strength models
The capability of being colored	Rough surface finish
Build models can be used for casting	
Low toxicity	
Relative material variety	

6. Fused Deposition Modeling (FDM)

In this system, a temperature-controlled head extrudes thermoplastic material layer by layer. A filament of a

Fig. 3: Schematic diagram of Inkjet-based system

thermoplastic polymer material feeds into the temperature-controlled FDM extrusion nozzle head, where it is heated to a semi liquid state. The motion of the nozzle head is computer controlled and is used to trace and deposit the material in ultra-thin layers onto a fixtureless base. The final model is built up layer by layer, and the material solidifies within 0.1s after being ejected from the nozzle and bonds to the layer beneath. This entire system works within a chamber that is held at a temperature just below the melting point of the proposed material. The supporting structures and overhanging geometries are later removed by cutting them out from the object.¹⁴ The advantages and disadvantages of this technique are described in Table 4.

Table 4: Fused deposition modelling

Advantages	Disadvantages
Direct wax pattern	Support structure must be removed
Multi-color part	Rough surface finish
Speedy procedure	Thermoplastic material only
	Not 100 percent dense

7. Selective Laser Sintering (SLS)

In the SLS method, layers of a particular powder material are fused into a 3D model using a computer-directed laser (Figure 4).⁴ A roller distributes the powdered material over the surface of a build cylinder. The powder is spread layer-by-layer on top of the preceding hardened layer and sintered repeatedly with a laser beam.¹⁵ The advantages and disadvantages of this technique are described in Table 5.

8. Selection of RP System

As discussed above, every RP system has its strengths and limitations. A suitable RP machine needs to be chosen such that it matches up to satisfy maximum requirements. Criteria quoted by Zein et al.¹⁶ and Xiong Z et al.¹⁷ for system

Table 5: Selective laser sintering

Advantages	Disadvantages
Fast fabrication time	Large tolerance
Low material cost	Lower strength models

Low toxicity	
Relative material variety	

Fig. 4: Schematic diagram of selective laser sintering

selection include: Application purpose, time constraint, cost, materials availability, accuracy, surface finish, and so on.

8.1. For example

While planning a surgery, an RP system, like SLA or FDM, enables us to use different colours to highlight and enhance the visualization of critical structures; hence, be preferable. Similarly, for designing a drilling guide for implants, SLA built model resins have visualization benefits due to their translucent nature.

When building speed is a consideration, the SLA machine is more opted for than the FDM machine. When surface quality and detailing is a significant concern, SLA followed by SLS is preferred. The FDM serves as an economical option.

9. Applications of RP in Dentistry

9.1. Applications in endodontics

The invention of RP has found tremendous applications in endodontics.¹⁸

9.1.1. Guiding the canal

Successful endodontic therapy requires a thorough understanding of root canal anatomy and its variations. In cases of complex root canal anatomies, 3D visualization of the canal through digital reconstruction of tooth model can be simulated through RP technology to achieve the precise

working path of the root canal.¹⁹

9.1.2. Accurate diagnosis of the lesions

In cases of root resorption, clinical and radiographic examination provides only a rough outline of the lesion that may not be continuous with the pulpal cavity. Rapid prototyping in these kinds of scenarios provides three dimensional view of the lesion and assists accurate diagnosis.²⁰

9.1.3. Autotransplantation

Earlier in cases of autotransplantation, the extracted donor tooth is used a guided template for the preparation of the recipient site. But with the advent of rapid prototyping, fabrication of a computer-aided surgical guide for the recipient site is possible. Adopting this new technique has led to a decrease in procedural duration and intraoperative errors.²¹

9.1.4. Endodontic training and research

It can evaluate the efficacy of the newer root canal systems in preparing curved canals of 3d printed tooth models.¹⁸

9.2. Applications in prosthodontics

9.2.1. Wax pattern fabrication

Traditionally, wax pattern making is the most labor-intensive step during the fabrication of crowns and RPD frameworks. With this technology, a new approach to automated wax patterns is now available in the field of prosthodontics. This simplified the traditional age-old technique of hand-made wax patterns. The advantages of automatic wax-up include:

1. High production rate of 150 crowns/hr by dental laboratories
2. Quality control of the wax copings is improved, resulting in the high precision fit of the crowns in the oral cavity.²²

9.2.2. Direct metal prosthesis

Fabrication of high precision metal parts with RP technologies such as selective laser melting (SLM) and SLS technology are used. Dental prostheses processed by employing SLS/SLM technique are appropriate for their complex geometry and their capability to be customized. This procedure eliminates the extensive manual pre and post-processing steps.²²

9.2.3. All ceramic restoration fabrication

The direct inkjet fabrication process has been anticipated using a slurry micro-extrusion process for the fabrication of an all-ceramic crown. This innovative method is a good CAD/RP system with a remarkable ability to produce

high precision fit all-ceramic crowns. The other advantages include cost competence and minimum material intake.²²

Complete dentures:

In complete denture situations, RP technology can be used for:

1. Establishing a 3D graphic database of artificial teeth positioning.
2. Getting 3D data of edentulous models and rims in centric relation.
3. Exploring a CAD route and developing software for complete denture finishing.

9.2.4. Maxillofacial prosthodontics

A wax prototype sculpted on the stone cast by using the free-hand technique can be eliminated using this RP technique. The 3D model of the patient's face (reconstructed with the CT data) can be used, and the technology can be applied in the following areas.²²

9.2.5. Fabrication of obturators, auricular and nasal prosthesis

1. Manufacturing of surgical stents for patients with large tumors scheduled for excision
2. Manufacturing of lead shields to protect healthy tissue during radiotherapy treatment
3. Fabrications of burn stents, where the burned area can be scanned rather than subjecting delicate, sensitive burn tissue to impression-taking procedures.

9.2.6. Implants

Achieving an ideal implant position is one of the key criteria determining implant success. Computer-aided designing and fabrication techniques employing implant simulation software provide a preoperative view of anatomical structures and restorative information, thus improving the procedure's outcome.

Guided implant surgery applies these digital techniques using drill guides processed by stereolithographic rapid prototyping through which implants are positioned with minimal surgical exposure of bone or even with a flapless approach. The advantages of the less invasive flapless surgical procedure include the following:

1. Shorter duration and facilitation of the surgical procedure.
2. Faster and less complicated recovery.
3. Enhanced esthetic results.

9.3. Application in Oral and Maxillofacial Surgery

The length and shape of the grafts to be used in surgical procedures are estimated through the surgical models. Customized plates can be pre-produced to hold the future bone graft, thus facilitating the surgical procedure and

saving intra-operating time. Also, the tumor areas can be coloured using stereolithographic techniques to visually establish their extension and clarify their relationship to the alveolar nerve in the mandible and hard surrounding structures, such as paranasal sinuses, orbit, etc.²³

Prototypes can and should be used in several situations such as: -

1. Evaluation of asymmetrical features
2. Reconstruction of symmetrical structures using mirroring
3. Fracture assessment
4. Modelling rigid internal fixation plates and screw selection
5. Modelling osteogenic distracters
6. Calculation and adaptation of bone grafts
7. Tumor assessment
8. Fabrication of surgical guides

9.4. Applications in Orthodontics and Dentofacial Orthopaedics

1. **Diagnosis and Treatment Planning-** Faber et al. state that RP is especially beneficial in cases with impacted teeth and helps understand the impacted tooth's exact position in relation to its surrounding structures.²⁴
2. **Fabrication of Removable Appliances and aligners** is easier and more accurate using the CAD/CAM technology. Lee et al.²⁵ described a technique where a polyvinyl chloride impression was used and converted into a 3D model in STL format directly using a CBCT image. This method was cheaper, with fewer manual errors when compared to the conventional technique of laser scanning and digitization of human tissues. The prototype is created using the SLA technique, and the aligner is built-in layered fashion using photosensitive liquid resin.
3. **Custom-made Trays-** It assists in the fabrication of custom-made trays in case of indirect bonding. Here, virtual bracket positioning is done on the software-generated digital model. Then using RP technology, trays are created.
4. **Lingual Orthodontics-** Customised lingual brackets can be produced using knowledge of RP technology. This facilitates direct bonding and easier positioning of the brackets onto the tooth surface.
5. **Orthognathic Surgery-** 3D models made using SLA helps understand the accurate positions of anatomical landmarks. Computerized orthognathic surgeries serve special importance in asymmetric cases where discrepancies can be measured and manipulated directly on the models. Mock surgery done on these models can help achieve more efficient post-operative results. Literature also suggests using the RP technique to create a 3D model of the jaws in Distraction

Osteogenesis cases.

10. Bioengineering Research in Dentistry

Tissue engineering is an important genre of treatment when attempting craniofacial reconstruction. RP technique has been proposed for bioprinting of tissue analogs and organ analogs. Features such as the possibility for multicolour printing provide us with added benefits during the arrangement and positioning of multiple cells.⁵

11. Scope of RP

Rapid Prototyping is comparatively a recent advancement with much scope for improvising the exactness, speed, and consistency. Further research needs to be conducted to widen the horizon for materials used in prototype construction. The current cost of the RP system is another area that needs to be dealt with.⁵

12. Conclusion

The ever-growing arena of digital services used for the automated production of dental prosthesis requires knowledge, skill sets and time to master the technology. As dentistry continues to move from analog to digital workflow, it may be time to evaluate state of the art and realize that it is not the computer that makes the decisions-it's only a tool to help clinicians make appropriate decisions and improve their decision with clinical outcomes.

<https://doi.org/10.18332/popmed/131263>

ABSTRACT

INTRODUCTION The perspectives of students towards their learning environment has seldom been in introspect in Indian dental institutions, which are against the advocacy of international dental education working groups. The aim of this study is to document students' perceptions of their learning environment in two of the thirteen teaching dental institutions in the state of Andhra Pradesh, India.

METHODS This qualitative study, involving focus group interviews, was conducted among undergraduate dental students in two teaching dental institutions in the state of Andhra Pradesh. Theoretical sampling was done with concurrent conduct of purposive sampling for focus group interviews and two researchers who participated in the pre-session were involved in moderating the interviews, which consisted of groups of six to eight participants. All the focus

group interviews were audio-taped and transcribed. The transcripts were analyzed using general inductive approach to extract themes.

RESULTS Problems in lectures and in the clinical learning environment, dissatisfaction with evaluation processes and poor academic drive were identified as the major themes responsible for negative learning outcomes. Some of the responses given by the students highlighted their disinclination towards receiving feedback and emphasized the need to move away from the authoritarian approach in teacher–student interactions. Evaluation is a major domain where reforms are necessary, as opined by the students.

CONCLUSIONS The perspectives of students towards the learning environment has seldom been in introspect in Indian dental institutions, which may have a substantial negative impact on students' attitudes and efficiency.

INTRODUCTION

Education is a word that is intriguing, even though it is rather familiar. The meaning assigned or attributed to the word is more belief bound than fact bound. In the rapidly evolving stream of education in healthcare, it appears that transfer of knowledge is the sole purpose of education, with application of this knowledge to real-world scenarios as a potential consequential outcome. However, the learning process does determine the acquisition of abilities that enable an individual to deal with the real world in a constructive way. The relevance of the learning process to socially desirable outcomes only increases for education in healthcare in light of the social roles the healthcare students assume in the future¹.

Initially there was refusal from medical schools to

incorporate dental education in their curricula, which could find its rationale in the opinions of some groups that the independent establishment of dental schools would be more practical as medical schools may be unwilling to offer the requisite physical space and expensive equipment for the greater technical and mechanical training involved in dentistry². From those times, dental education has gone far during the last century to establish dentistry as one of the most sought after and celebrated healthcare professions. However, the quality and recognition of dental education has not been the same worldwide, leading to evolution of the accreditation process for foreign-trained dental graduates in some nations³. International dental education working groups have highlighted the relevance of students'

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

perspectives in the quest of improving dental curricula and have urged that students' views be considered in dental education planning and development^{4,5}.

In the Indian context, it is evident that there has been a phenomenal growth in the number of dental colleges over the past couple of decades⁶. Currently, there are 313 functional dental institutions in the country making India one of the countries that produces the largest number of dental graduates every year⁷. In this regard, it is essential to continuously review the way in which the curriculum is being implemented at the institutional level to keep the standards of dental education in India abreast with the global dynamics in dental education. It must also be understood that this responsibility of program evaluation and refinement of curricula, as necessary, must occur both at the institutional and national level. Unfortunately, it appears that most of the dental institutions in India have not focused on this responsibility. Seldom has it been introspect how well the curriculum is being followed and how satisfied the students, the main stakeholders, are with the learning environment and what their problems are in following the curriculum⁸. Regular evaluation and critical appraisal are as cardinal as the design and implementation of these curricula. With this background, the objective of this qualitative study was to document students' perceptions of the learning environment in two of the thirteen teaching dental institutions in the state of Andhra Pradesh.

METHODS

The dental curriculum in India requires that the dental students undergo clinical training in the third and fourth (final) year of the course and, after successful completion, are required to follow a one year paid rotating internship that must be completed for the students to graduate⁹. This qualitative study involved focus group interviews of dental students in two teaching dental institutions in the state of Andhra Pradesh, India. Focus group interviews are well documented in the literature as effective methods for gaining a deeper insight into the construct of interest. In India, undergraduate dental education has a 5-year curriculum, where the first two years are devoted to basic sciences and pre-clinical exercises in dentistry. Clinical training is offered in the third and fourth years of the curriculum; the fifth year of the curriculum requires the student to complete a rotatory internship with scheduled posting in all the specialties before being awarded a Bachelor of Dental Surgery degree (BDS). In this study, each focus group had representation from all clinical years (i.e. third, fourth and internship); all the participating students were given a pseudonym to ensure anonymity. The number of participants in each focus group ranged from 6 to 8, as recommended in the literature. Two researchers were involved in moderating the interviews. The interviews were semi-structured and a loose set of questions were prepared beforehand to facilitate the discussion. Table 1 shows the interview guide used in this study, which is not

Table 1. Interview guide

As a student, what have been your personal experiences over the years with lectures given by faculty members?
You have entered clinical postings in the third year of your BDS program. Since then, have you ever faced problems in clinical learning?
What are the most common issues that preclude your comprehensive learning in clinics?
How satisfied are you with the current student evaluation processes being followed?
Do you feel that there is a need for objective assessment methods for evaluation of students' performance?
Are you really interested to demonstrate excellent academic performance?

exhaustive as other questions emerged from the interaction between the moderator and the study participants. This set of questions was prepared by a group of four experienced dental educators and included the following constructs: teaching skills and attitudes; clinical learning environment; assessment criteria in practice; and challenges in meeting requirements. A pre-session was conducted before the focus group discussions so that the participants and moderator became acquainted. All the focus group interviews were audio-taped and transcribed by two members of the study team. The transcripts were given to two researchers for independent open coding to extract thematic constructs from the discussion. All the themes were reviewed by both researchers and consensus was obtained wherever there were differences in coding.

Theoretical sampling was done with concurrent conduct of purposive sampling for focus group interviews, data collection, and data analysis, which identified if there was a need for further recruitment of participants. Data saturation was considered to have been achieved after seven focus groups were interviewed in Institution A and six in Institution B. The study was conducted between October and November 2019. Ethical approval for the study was obtained from the institutional review board of SIBAR Institute of Dental Sciences and verbal informed consent was obtained from all the participating students with prior information to and approval from the Institutional Review Board (IRB). It was explained to the IRB that the need to obtain written informed consent would limit the rate of participation, given the objectives of the study and that the study participants had yet to complete their course. A script of verbal consent was reviewed and deemed satisfactory by the IRB.

RESULTS

The mean age of the study participants was 22.6±1.71 years, with no significant differences between institutions. The

average duration of the focus group interviews was 64.7±8.2 minutes. Within each of the focus groups, there were more female than male students. The following thematic constructs were developed from the responses to determine negative learning outcomes: 1) problems in lectures; 2) problems in clinical learning; c) dissatisfaction with evaluation processes, and d) poor academic drive.

The following are some of the responses in the students' own words. Some of the responses were translated for convenience in presentation, since both the local language Telugu and English could be used in the focus group interviews. After translation, the responses were reviewed by two bilingual experts for any changes in the meaning of the responses. Few of the responses that were representative of the general opinion expressed by students were presented in a construct sense.

Problems in lectures

The majority of the students expressed concerns about the lectures. While the importance of theory classes as influencing the conceptual foundations in a discipline was well acknowledged by the students, it was the way in which theory classes were being conducted that received criticism. Almost all the theory classes were reported to be power point presentations with nominal use of other teaching aids. The following are some responses obtained from students:

'Some of the teachers read from power point slides. We are asked to take notes from the slides. I never felt engaged in the class'

'We want teachers to be interactive. Theory class must include questions. In classes where the teachers question, I feel more engaged'

'Some topics require video demonstrations in the class for us to better understand. Certain practical works are understood better by videos than reading from a power point'

'Is it mandatory for a lecture to be completely in English? I feel some faculty convey the message better if they have the opportunity to use both the languages, English and Regional'

'Afternoon theory classes are very difficult to concentrate. Either we keep thinking about what had happened in the clinic that day in the morning or we sleep'

Problems in clinical learning

The problems in clinics were reported to be affecting the interest and confidence of students to perform the clinical procedures being taught and practiced. It was reported that the students are not very comfortable at and do not enjoy going to clinics.

'In my opinion, the main problem in clinics is demos. When any demo is given, 13 of us are standing around the professor and not everyone can see the work. Demos should be given for small groups of 4 or 5'

'Sometimes, my instructor does the work for me. At that moment, I feel happy. But if the same work has to be done under a different instructor in my second posting, I regret

about why I had not learnt that work in the previous posting'

'We don't want our work to be done by the instructors. We want the instructor to stay beside and help us through'

'My fear is that my instructor would belittle me if I ask a stupid doubt. There was an occasion when I was made fun of in front of the patient after which the patient refused to get the examination done and walked out'

'Feedback is very important for us to improve. When I joined here, I was very enthusiastic about interacting with staff and seek feedback. The scenario has changed now. I don't know whether it is because of a legacy that is transferred from the previous batch or due to some bitter experiences we had, but I am not keen in receiving feedback now'

'I think we should be allowed to go to clinics to complete the unfinished quotas whenever we find time. My professor says "you don't have to sacrifice theory class from another department and come here". But no one will be there in the clinic after the theory class in the afternoon. How can I ever finish my quota like this?'

Dissatisfaction with evaluation processes

Evaluation processes adopted by the faculty were opined by the students to be far from objective. It was reported that comparison instantly comes where competition exist, and it is discouraging to see comparatively better grades being given for under-performing students.

'There is definitely partiality in evaluation. We bother more about who is the internal for the practical examination than what all topics to be prepared for'

'Some students move closely with faculty. I feel it can be inconvenient both for fellow staff and the students as well. But I don't know whose mistake is it more'

'You can compare marks in pre-clinical examination and final year examinations. The huge difference in the marks of a student is because of the difference in examiners on the two occasions'

'If everyone is getting highest marks, the students who are really interested to perform will lose that enthusiasm. I know this has happened'

'If you see the theory marks of the students who got highest marks in practical, they are less. There must be something wrong, no!'

Poor academic drive

At the end of each focus group interview, the students were asked if they were really interested to do well and perform academically.

'Most of us are not very keen. Many students want to just get through'

'Yes, obviously everyone wants to perform well. I don't really understand the question'

'I know why this question is being asked. There are things which the students need to change as well. It is not right to give suggestions for others to improve when you yourself are not prepared enough to excel'

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

'I have written so many internals. Every time I feel that I should write this internal well. But I have never prepared for an internal and never passed one. There is a notion that we will get at least 5 marks for the 10 marks allotted for internals. I don't know how true it is.'

'As far as internals are concerned, we just need to attempt all of them. There is no time to prepare and study, and what I know is we don't really have to pass.'

DISCUSSION

The changing scenario of education in healthcare, globally, shifted the focus from preparing trainees to developing an institutional culture, with administration, faculty, and the students being recognized as accountable for the latter¹⁰. Literature suggests that faculty development programs (FDPs) in dental education are almost nonexistent in India¹¹. A Master's in Dental Surgery (MDS) is a clinical training program wherein the necessary skills for educating and training students are not fully imparted, so if one is interested in teaching, the faculty needs to learn pedagogical techniques through FDP or another way. Therefore, FDPs are essential and must be observed as part of the institutional curriculum. Most of the problems faced by students relating to classroom teaching in this study could be comprehended as being consequential to the lack of initiatives such as FDP. Engaging the students in the class translates to facilitating active learning and allowing for intuitive appreciation of instantaneous feedback.

Since there were no large differences in the opinions of the students, and it was not the intention of this study to compare institutions but to try and develop an understanding of the learning environment from the students' perspective, the responses were not categorized based on the institution. This choice was made since these institutions follow the same curriculum and offer admission to students predominantly from the state of Andhra Pradesh, India. Moreover, initial review of the participant responses did not show marked differences in opinions relating to different aspects of the learning environment. Few incidents were identified in the study where students were reportedly mistreated in the clinics. It was recognized that the students did not report these incidents before and opined that it was senseless to report the incidents. Similar findings were reported by the Association of American Medical Colleges, where students refrain from reporting mistreatment thinking that the incident does not carry enough importance, fearing reprisals and believing that the incidents would be ignored¹². A study on students' perceptions of the clinical learning environment in New Zealand noted that students were not satisfied with the feedback received¹³. Consistent with the above observations, students in this study expressed disinclination towards receiving feedback.

It is imperative for both faculty and students to understand that misinterpretations and uncertainties are inevitable in clinical practice as the presentation of a

clinical condition differs from individual to individual and so does the provision of care. It was suggested by Perry that empathetic teachers in a clinical environment who admit their uncertainty in a given clinical situation helps students in the much-needed transition from right-wrong dichotomy to acceptance of uncertainties¹⁴. Furthermore, the authoritarian attitude of teachers towards students has the unwanted consequence of the attitude being adopted by students towards their patients. It is well documented in the literature that students who face public humiliation and considered unworthy do not empathize with patients¹⁵. In this regard, it becomes the responsibility of any healthcare institution to focus on student-centered teaching which translates to patient-centered care being observed by the students or trainees.

Globally, assessment of students' academic performance is an area of professional education that has undergone a multitude of changes over the past few decades¹⁶. However, the assessment criteria in most dental educational institutions in India continue to be the same, with no objective methods in place to evaluate the clinical skills demonstrated by the students. It is essential to discern that assessment constructively navigates learning. It is only when the influential role of assessment in motivating the students to learn is recognized that the need for appropriate assessment criteria relevant to the domain to be assessed is understood. The dissatisfaction expressed by the students with evaluation in the present study emphasizes the need to institute more objective assessment criteria. International experience suggests that students show better interest and report better learning when marking and grading are not in concomitance with the learning process^{13,17}. Inclusion of Objective Structured Clinical Examination (OSCE) in the dental curricula would be beneficial in eliminating prejudice and allows everyone to be assessed by the same criteria¹⁸. Furthermore, use of portfolios facilitating students to reflect upon their own performance would facilitate better learning¹⁹. OSCEs are widely used in undergraduate dental education in European²⁰, American²¹, and Canadian dental education²². A study focusing on the integrated aspects of team-based learning with peer-to-peer teaching at the Harvard School of Dentistry reported that weaker students performed considerably better with less faculty involvement and more self-directed learning²³. These findings highlight the need for preparing customized teaching plans to stimulate students' quest for learning. Student Evaluation of Teaching (SET) is known to be an effective way for assessing faculty performance by the recipients themselves. When constructed and delivered in the right manner, SETs are acknowledged to be valid and reliable measures for assessment of faculty performance, and should be linked with annual salary increment or promotion of faculty members²⁴. The relevance of SETs in dental curricula has been widely discussed over the years, and can be considered for inclusion in the Indian dental educational context^{25,26}.

Strengths and limitations

The results from this qualitative study highlight the fact that students face challenges in the learning environment, which lead to negative learning outcomes, especially when the students demonstrate poor academic drive. Nevertheless, the temporal association between perception of problems in the learning environment and poor academic drive cannot be inferred from the results of this study. However, it is certain that the responses given by some students demonstrating their mediocre interest to perform well academically may not entirely be attributed to the learning environment but could be circumstantial, especially in light of the growing debate for the future of the dental profession in India.

The findings of this study provide some solutions and offer a framework for the conduct of future research to better understand the guiding factors for students' perceptions of the learning environment based on what was documented here. The study also highlights the need for regular institutional reviews of curricula in dental education. Though it cannot be claimed that the findings of this study can be generalized to all teaching dental institutions in India, it is most likely that they apply across dental institutions.

CONCLUSIONS

In countries like India where the burden of oral diseases is very high, it is pertinent that technically well equipped, socially empowered, and cognitively empathetic dental professionals be prepared to meet the ever-increasing need for dental healthcare. Conducive learning environments are necessary for the preparation of such professionals, which demands commitment from educators, administrators and students. Regular introspection of the strength and implementation of the curricula and documentation of the perceptions of the stakeholders demonstrate the need for this commitment and provide an opportunity for better dental education. In a competitive world where mediocrity is not entertained, striving for excellence has become the norm. In this context, it is recommended that all teaching dental institutions develop institution-specific models for assessment of the learning environment and councils regulate the learning environment by instituting fundamental common norms across the dental institutions in the country.

Management of Extracted Human Teeth by Dental Students in East Coastal Region of India

Parveen Sultana Shaik, Suresh Chand Yaddanapalli, Srinivas Ravoori, Srinivas Pachava, Asha Lodagala¹, Nijampatnam P. M. Pavani

Department of Public Health Dentistry, Sibar Institute of Dental Sciences, Guntur, Andhra Pradesh, ¹Department of Public Health Dentistry, Dr Syamala Reddy Dental College Hospital and Research Centre, Bengaluru, Karnataka, India

Abstract

Background: Dental students practice on extracted human teeth (EHT) in their preclinical to learn professional and technical skills before performing dental procedures on patients. **Aim:** The aim of the present investigation was to assess the management of EHT among dental students in the east coastal region of India. **Materials and Methods:** A cross-sectional study was conducted on II, III, and IV Bachelor of Dental Surgery (BDS) students from five dental colleges in India's east coastal region, which were chosen using the fishbowl technique. Data was collected using a pretested, validated self-administered questionnaire and analysed using the Chi-square test, Mann-Whitney test, Kruskal-Wallis test, and linear regression. **Results:** A total of 649 students participated from five dental colleges, among them, 43.6% (283) were II BDS, 29.6% (192) were III BDS, and 26.8% (174) were IV BDS. About 66% of the participants do not know that the EHT are a source of infection; 22% of them noted that there was an incidence of infection with the use of EHT; 81.5% do not know that guidelines have to be given by the regulatory body/institution to handle EHT. Only 2% of the people think it was necessary to disinfect/sterilize EHT before use, while 33% of the study population felt that there was a need to wear mouth masks and gloves while working on EHT. In the study group, only 43% know that formalin was used as a storage/disinfecting medium for EHT and 80% of them experienced hazards due to chemicals used for storage/disinfecting medium of EHT. **Conclusion:** The results of this investigation stipulated that awareness, attitude, and practices of undergraduate students in relation to the handling of EHT were poor. However, deficiencies were observed in relation to teaching the materials and methods suitable for the management of EHT which reveals the need to incorporate the guidelines in their curriculum.

Keywords: Awareness, dental student, disinfection extracted human teeth, dental, practice management.

INTRODUCTION

Unblemished extracted human teeth (EHT) are utilized by dental graduates to create and hone their clinical abilities for treating patients. EHT are utilized for different purposes, for instance, like preparing ground sections to study histology of teeth, for learning endodontic procedures such as cavity preparation and root canal treatment, for learning crown preparation, and to evaluate microleakage of the restorative material and marginal integrity in crown preparation techniques.^[1]

Nowadays, typodont models are used as practical learning aids for dental students for dental students, permitting them to exercise certain dental procedures on the plastic teeth of a

model before really playing out the systems on live patients. Working on the extracted teeth results in achieving the same tactile sensation as like operating on the live case scenario. In middle- and low-income nations like India where the per capita income is less, extricated human teeth serve a low spending substitute to typodont that permits the students to utilize them for training.^[2]

Individuals handling EHT for preclinical training or clinical assignments must be conscious of the potential exposure to

How to cite this article: Shaik PS, Yaddanapalli SC, Ravoori S, Pachava S, Lodagala A, Pavani NP. Management of extracted human teeth by dental students in East Coastal Region of India. J Indian Assoc Public Health Dent 2021;19:206-11.

the blood-borne pathogens acquired from the extricated human teeth. Therefore, individuals who collect extracted teeth must decontaminate before using them. Various solutions have been used to store and transport extracted teeth. Of all the media, the most common ones are formalin, saline, hydrogen peroxide, and sodium hypochlorite. Since these liquids are easily available in dental clinics, they have become the obvious choice to store extracted teeth.^[3]

The Occupational Safety and Health Administration Blood-borne Pathogens Standard considers human teeth used for research and teaching purposes as a potential source of blood-borne pathogens.^[4] Since extracted teeth form a part of the human body before they are extracted, they are an obvious source of infection, and the Center for Disease Control (CDC) also recommends that the extracted teeth be treated as potential blood-borne pathogens. The CDC and prevention have adopted guidelines for infection control of extracted teeth used for research and teaching, requiring that teeth be sterilized before use, to minimize the risk of transmission of blood-borne pathogens.^[5,6]

While there are studies on the effectiveness of disinfectants, assessment of knowledge, attitude, and practice regarding the handling of extracted teeth among dental students are limited. Hence, this study was conceived with the intention to assess the knowledge, attitude, and practice regarding the handling of extracted teeth among the students of the dental colleges in the east coastal region of newly formed state of India.

MATERIALS AND METHODS

A cross-sectional study was carried out on the II, III, and IV bachelor of dental surgery (BDS) dental students among five dental colleges located in the east coastal region of Andhra Pradesh, India [Image 1]. There are 16 dental colleges in the state of Andhra Pradesh out of which 13 colleges are located in the east coast region where five colleges were selected randomly using the fishbowl technique.

A pretested, validated, self-administered questionnaire which was taken from the previous study was used to test the

knowledge, attitudes, and practices of students regarding the handling of EHT.^[3] Questionnaires were anonymous and filling the questionnaire was completely voluntary where consent was taken prior to the start of the study. The questionnaire was distributed and collected by a single investigator. The goal of the study was explained and students were left alone to fill the questionnaire. Ethical approval was obtained from the Institutional Review Board (IRB) with reference number 39/IRB/SIBAR/2019.

The questionnaire consisted of four sections, where the first section consists of demographic details and II, III, and IV sections include knowledge, attitude, and practice-based questions on the management of EHT.

Data were collected and statistically analyzed using Statistical Package for the Social Sciences (SPSS) version 25 (IBM, Chicago Inc., IL, USA). Descriptives, Chi-square test, Mann–Whitney test, Kruskal–Wallis test, and linear regression were done where $P \leq 0.05$ was considered as statistically significant.

RESULTS

Figure 1 shows the distribution of study participants in accordance to their academic year. Total study population were 649 students, among them 43.6% (283) were II BDS, 29.6% (192) were III BDS, and 26.8% (174) were IV BDS. Table 1 describes all knowledge, attitude, and practices in handling of EHT. Most of the study participants (66%) do not know that the EHT are a source of infection. About 22% of the participants noted that there was an incidence of infections such as respiratory problems, eye and skin irritation was reported with the use of EHT for educational purpose. Almost 81.5% do not know that guidelines are necessary to be given by regulatory body/institution to handle EHT. Only 36% of the students are aware of guidelines by a regulatory body regarding the handling of EHT and only 2% of the people think it was necessary to disinfect/sterilize EHT before use. Nearly 33% of the study population felt that there was a need to wear mouth mask and gloves while working on EHT. In the study group,

Figure 1: Distribution of participants according to their academic year

Table 1: Perceptions of the individuals regarding handling of extracted human teeth

Questions	Yes (%)	No (%)	Do not know (%)
Do you consider extracted human teeth as a source of infection?	6.5	27.5	66
Is there any incidence of infection noted with the use of extracted human teeth for educational purpose?	22	33	45
Do you think it is necessary to have guidelines by regulatory bodies/institutions to handle extracted human teeth	5.5	13	81.5
Are you aware of any guidelines by a regulatory body regarding handling of extracted human teeth?	36	64	-
Do you think it is necessary to disinfect/sterilize extracted teeth before use?	2	4	94
Is there a need to wear mouth masks and gloves while working on extracted human teeth for educational purpose/s?	33	10.5	56.5
Is the use of Formalin for storage/disinfection of extracted teeth hazardous?	43	34.5	22.5
Have you experienced any hazard due to the use of chemicals for storage/disinfection of extracted teeth?	80	20	--
Have you referred to any published scientific literature regarding the use of an appropriate medium for storage/disinfection of extracted human teeth?	11.5	88.5	--
Have you noticed any change in surface characteristics of the extracted teeth samples after storage in a disinfectant medium?	52.5	47.5	--

Questions	Dust bin (%)	Red color bag (%)	Yellow color bag (%)
How do you dispose of extracted human teeth after its use for educational purpose/s?	17.9	66.1	16

only 43% know that formalin was used as storage/disinfecting medium for EHT and 80% of them experienced hazards due to chemicals used for storage/disinfecting medium of EHT. Merely 11.5% of the participants referred to any published scientific literature regarding the use of an appropriate medium for storage/disinfection of EHT and 52.5% have noticed some changes in surface characteristics such as a change of color and surface texture of the EHT samples after storage in a disinfectant medium.

Figure 2 explains that majority of the students (56%) used hydrogen peroxide (56%) followed by usage of both formalin and H₂O₂ (11%), while 9% of them are using formalin as a storage medium to store EHT. Table 2 depicts the knowledge and attitudes of dental students in handling EHT according to their academic year. Second BDS (60.3%) and IV BDS (88.5%) students reported that they do not know that the EHT as a source of infection, while III BDS (78.2%) students did not consider them as an infectious source ($P = 0.001$). Second BDS (67.2%) and IV BDS (95.3%) students have disclosed that they were not aware of any guidelines by a regulatory body regarding the handling of EHT ($P = 0.001$); similarly, they have also proclaimed that they do not know whether it is necessary to disinfect/sterilize extracted teeth before use (72.4% and 100%, respectively, $P = 0.001$). Almost all the students of II BDS, III BDS, and IV BDS opted red color disposal bag to dispose EHT ($P = 0.42$).

The highest percentage of the students among all the 3 year use hydrogen peroxide to store EHT and it is statistically significant ($P = 0.005$) [Figure 3]. Table 3 elucidates that the mean rank of knowledge was more for females (310.07), while the mean rank of attitude (312.11) and practice (319.25) in participants were higher in males. Statistically significant results are seen in attitude ($P = 0.004$) between genders, but

Figure 2: Usage of various storage medium for extracted human teeth by the dental students

there was no statistical significance in knowledge ($P = 0.194$) and practice ($P = 0.208$). The mean rank of knowledge was higher in III BDS students (356.39) when compared to II BDS (294.94) and IV BDS (339.26) ($P = 0.001$), where the mean rank of attitude was observed to be more in II BDS students (357.60) followed by IV BDS (324.40) and III BDS (227.50) ($P = 0.001$), and the mean rank of practice score was more in IV BDS (348.02) compared to III BDS (335.36) and II BDS (303.82) which was statistically significant ($P = 0.032$).

Knowledge and practice scores in dealing with EHT increase as the academic year progresses ($B = 0.181, P = 0.004$ and $B = 0.589, P = 0.004$, respectively), but attitude score showed an inverse relationship ($B = -0.213, P = 0.002$) [Table 4].

DISCUSSION

Extracted teeth contain virulent microorganisms capable of causing diseases such as hepatitis B virus (HBV) and human immunodeficiency virus (HIV).^[4,7,8] Even after the complete

Chi-square test, *Statistically significant

Figure 3: Choice of storage medium for extracted human teeth according to academic year of the participants

removal of saliva and blood, HBV might remain contagious up to 6 months, while under the similar conditions, HIV can remain infectious for 4–8 weeks.^[7,9] Since EHT may harbor potential pathogens, proper handling of EHT in the preclinical’s is important for educators and the students.

Developed countries such as Australia and the UK have legislation to limit the usage of EHT for the purpose of educational use with the help of the patient/legal guardians written consent, whereas in India, we do not have such legislation and acts to abide, while EHT were used for the educational purpose by honing their clinical skills rather disposing in the clinical waste.^[10]

In the present study, 66% of the study participants do not know that EHT are a source of infection which is lower when compared to the other studies done by Kumar *et al.*^[11] (97%), Hashemipour *et al.*^[12] (95%), Deogade *et al.*^[13] (90.2%), and Amith *et al.*^[14] (88%), whereas it was higher when compared to studies done by Omar OM *et al.*^[15] (55.6%) and Sethi *et al.*^[16] (57.4%). This could be due to the fact that usage and handling of EHT was considered as a conventional practice while they are easily accessible, affordable while there were no guidelines framed in the curriculum on the management and utilization of EHT.

In the current study, 81.5% do not know that guidelines are necessary by regulatory body/institution to handle EHT which is in contrast with the study done by Smitha *et al.*^[3] (84.7%) and Sethi *et al.*^[16] (83.3%), who reported that it is necessary to have guidelines by regulatory body/institution. In contrast to Smitha *et al.*^[3] study, only a meager current study participants (36%) are aware of the guidelines on handling of EHT. (80.6%). In this study, 94% of the study participants do not know that it is necessary to disinfect the teeth which is in contrast with the studies done by Amith *et al.*^[14] (93.2%), Deogade *et al.*^[13] (91.5%), Smitha *et al.*^[3] (90%), and Omar OM *et al.*^[15] (87.9%) who reported that they know that it is necessary to disinfect the teeth.

Practice score ^a	0.589	0.206	0.004*	0.185	0.994

^aDependent variable, *Statistically significant ($P \leq 0.05$). CI: Confidence interval, SE: Standard error

About 56.5% of the current study participants do not know that there was a need to wear mouth masks and gloves while working on EHT where dissimilar results were observed in the studies done by Amith *et al.*^[14] (90.7%), Deogade *et al.*^[13] (95.3%), and Smitha *et al.*^[3] (91.7%) which reveal that the study participants are had not kept themselves updated about the latest guidelines for safety. About 52.5% of the participants in the study have noticed some changes in surface characteristics after storing in the disinfectant medium, while similar results were found in the studies done by Smitha *et al.*^[3] (42.7%) and Sethi *et al.*^[16] (54.8%), this could be due to the fact that dentin hardness decreases as both organic and inorganic constituents are affected by the various disinfection methods.

Most of the study participants had used hydrogen peroxide (56%) and only 9% of them used formalin as a storage medium for EHT, comparable to the studies done by Amith *et al.*^[14] (93.8%), Kumar^[11] (81.7%), Deogade *et al.*^[13] (57%), Smitha *et al.*^[3] (42.2%), and Omar OM *et al.*^[15] (18.8%). Despite the evidence demonstrated by numerous studies, students still use hydrogen peroxide because of its feasibility, availability, and cost-efficiency.

In the current study, 22% of them disclosed that they have experienced discomfort due to the usage of chemicals for storage/disinfection of EHT, whereas a higher percentage (61.1%) of them reported the same in the study done by Amith *et al.*^[14] Exposure to EHT stored in formalin may cause irritation of the eyes, nose, and throat since they were absorbed through the epithelium due to the fact that tooth preserved in formalin

releases toxic vapours that may cause local irritation, so when working with preserved EHT requires safety precautions such as wearing protective equipment and opening the container preserving EHT in a safe, well ventilated area.

Majority of the participants have disposed EHT in the red bin (66.1%) which was in contrast with the studies done by Omar OM *et al.*^[15] (27.2%), Riswana^[17] (10.9%), and Smitha *et al.*^[3] (27.2%). Only 16% answered correctly that EHT have to be disposed in yellow color-coded bags which depicts a lack of knowledge among the dental students on disposal of EHT.

Almost 88.5% of the participants proclaimed that they have not referred to any published scientific literature regarding the use of an appropriate medium for storage/disinfection of EHT and similar results are observed in the studies done by Smitha *et al.*^[3] (81.3%) and Omar OM *et al.*^[15] (53.8%). As a source of knowledge, self-reading of articles and research papers was not so common in this sample community. This was demonstrated in their response and practice of using a suitable medium or procedure to sterilize/disinfect EHT. With this background, students need to be educated with the published literature. This often highlights incomplete knowledge in the dental curriculum on this subject that should be addressed in depth.

CONCLUSION

Patient care is the very essence of what dentists do, and it is the way dental students truly learn to become dentists. The results of this investigation warranted that the awareness and knowledge of undergraduate dental students on the management of EHT

were found to be deficient. However, proper teaching, training, and education are necessary to handle, storage, and practice of EHT for their educational purpose. The other safety measures such as the use of gloves, masks, and safety eyeglasses should be stressed while practicing preclinical work on these teeth. Incorporation of guidelines on disinfection, storage, usage, and disposal of EHT should be included in their curriculum.

Depression, suicidal ideation, and suicidal behaviors among dental students of Neo-state capital region in India

Nijampatnam P. M. Pavani, G. Anirudh¹, Nandita Rani Kothia²,
Parveen Sultana Shaik, K. Krishna Priya³, Suresh Chand Yaddanapalli

Abstract:

BACKGROUND: The challenges of dental education place students at high risk of stress. Because dental education is a highly demanding and challenging course, placing heavy demands on the mental resources of the students, making them vulnerable to high levels of stress, this study aimed to determine the prevalence of depression, suicidal ideation, and suicidal behaviors in dental students.

MATERIALS AND METHODS: A descriptive cross-sectional study was done on a convenience sample of 388 dental students in a teaching dental institution. Data were collected using standard, prevalidated, self-administered questionnaires (Patient Health Questionnaire-9 and Suicidal Behaviours Questionnaire-Revised [SBQ-R]). Analysis was done using SPSS version 20. Descriptive statistics, Chi-square test, and logistic regression were performed.

RESULTS: At least half of the students were in major depression with different levels of severity. When students from different years were analyzed, majority from each year fell under II and III categories ($P < 0.001$). Most of the students reported that they do not have any suicidal ideation or behavior (SBQ-R). Nearly 16% of the students either presented the threat of suicidal attempt or likelihood of suicidal behavior in future. Almost 13% of the dental students thought of killing themselves in the past year for at least two times. Around 16% of them expressed to someone about their thought of committing suicide.

CONCLUSION: Even though depression and suicidal tendencies were not prominent in dental students, there is a need to shed light on those who responded positively and take necessary reforms to relieve academic stress.

Keywords:

Postgraduates, stress, suicidal tendency, undergraduates

Introduction

Suicide is the act of killing yourself, most often as a result of depression or other mental illness.^[1] Depression is a key risk factor for suicide; others include psychiatric disorders, substances used, chronic pain, a family history of suicide, and a prior suicidal attempt. Impulsiveness often plays a key role among adolescents who take their life.^[2] The prevalence

of suicide is often underestimated due to cultural, political, and economic circumstances. Recent reports inform that around a million people die by suicide annually, representing an annual global age-standardized suicide rate of 11.4/100,000 populations (15.0 for males and 8.0 for females),^[3] which is one person every 40 s and many more may attempt suicide. Suicide occurs throughout the lifespan and is the second leading cause of

death among 15–29 year olds globally.^[2] According to the data by the accidental deaths and rate of suicides in India for the year 2019, the percentage distribution of suicide victims by the students was 10.4%, whereas that of for the year 2019 was 7.4%.^[4]

While the link between suicide and mental disorders in particularly, depression, and alcohol use disorders is well established in high-income countries, many suicides happen impulsively in moments of crisis with a breakdown in the ability to deal with life stresses.^[5] Nowadays humans are exposed to more stress than ever due to increasing competition and various environmental factors. The challenges of dental education place students at high risk of stress.^[6,7] Dental education is a highly demanding and challenging course, placing heavy demands on the mental resources of the students, making them vulnerable to high levels of stress.^[8] Suicidal ideation aids the thoughts of harming or killing oneself as it is a nonfatal, self-inflicted destructive act with explicit or inferred intent to die. Suicidality refers to all suicidal-related behaviors and thoughts including completing or attempting suicide, suicidal ideation, or communication.^[9]

Depression refers that common mental disorder, characterized by persistent sadness and a loss of interest in activities that you normally enjoy, accompanied by an inability to carry out daily activities, for at least 2 weeks.^[10] Hence, recognizing depression levels in vulnerable dental students plays a crucial role in making changes in the present dental curriculum. The aim of the study is to determine the prevalence of depression, suicidal ideation, and suicidal behaviors in dental students; to assess whether there is any association between depression and suicidal ideation; and to evaluate whether gender is a predictor of prevalence of these conditions.

Materials and Methods

Study design and setting

A descriptive cross-sectional study was done among dental students from a teaching dental institution of southern India in the month of February 2020.

Study participants and sampling

A total of 388 dental students were included in the study using convenience sampling method. Students from the clinical years (third and final years of undergraduation and postgraduation) were only included because they are the students who deal with the patients and are under high stress levels compared to the students from nonclinical years, and the study was not conducted during university exams to avoid exaggerated reporting.

Ethical considerations

Prior to the study, study details were explained and ethical clearance was obtained from the institutional ethical committee (239/IRB/SIBAR/2019).

Inclusion and exclusion criteria

students who were willing to participate and present on the day of data collection were included in the study, whereas students who were absent on the day and not willing to participate were excluded from the study.

Data collection tool and technique

The study pro forma has two part: the first part consisted of information regarding age, gender, and year of the study and the second part consisted of standard, self-administered, structured questionnaires (Patient Health Questionnaire^[11] and Suicidal Behaviours Questionnaire–Revised^[12]) to collect data regarding depression, suicidal ideation, and suicidal behavior [Annexure 1]. Patient Health Questionnaire (PHQ-9) is a self-reported depression assessment specifically developed for use in primary care. The questionnaire was taken from a previous study^[11] which was pretested and validated in 233 adolescent Indian students aged 14–18 years. It has good diagnostic accuracy with a sensitivity of 87.1%, a specificity of 79.7%, good content validity, good 1-month test–retest reliability ($r = 0.875$), high internal consistency (Cronbach's $\alpha = 0.835$), and high convergent validity with the Beck Depression Inventory ($r = 0.76$; $P = 0.001$).^[11] This depression questionnaire consists of 9 items to assess the level of depression and a 10th functional health assessment item to know the perceived difficulty of the problems faced by the individuals. Each of the 9 items was scored on a 4-point Likert scale ranging from score 0 (not at all) to 3 (nearly every day). After obtaining the total score by adding the scores of the individual 9 items, the severity of depression was graded as follows: 0–4 (minimal), 5–9 (mild), 10–14 (moderate), 15–19 (moderately severe), and ≥ 20 (severe).^[11] Suicidal Behaviours Questionnaire (SBQ) consists of 4 items, of which responses of item number 2 and 4 were measured on 5-point and 6-point Likert scales, respectively. For item no. 2, the responses ranged from “never” to “very often.” For item no. 4, the responses ranged from “never” to “very likely.” Item no. 1 and 3 had 6 and 5 responses, respectively. It was validated in psychiatric inpatient adolescents, high school students, psychiatric inpatient adults, and undergraduate students. SBQ has good diagnostic accuracy with 93% sensitivity and 95% specificity.

Statistical analysis

Data analysis was done using IBM Corp. Released 2017. IBM SPSS Statistics for Windows, Version 25.0 Armonk, NY: IBM Corp. Descriptive statistics, Chi-square test, and logistic regression tests were performed.

Results

Most of the study participants were female (74.7%) and are undergraduate (76%), while majority of them belonged to internship (28.6%).

Table 1 shows that 58.3% of the participants had minimal to mild depressive symptoms, while most of the students felt that any of their depressive symptoms made it “not difficult at all” (33%) or “somewhat difficult” (56.2%) to do their work, take care of things at home, or get along with other people.

Table 2 shows that 35.8% ($n = 139$) of students reported that they had a thought of killing themselves; of those, 12.6% of the individuals had a suicidal plan at least once, while 3.4% have tried to attempt, whereas 32.9% of the students have the thought of attempting suicide at least once in the past year. Out of the 139 participants with the suicidal intention, 63 members have discussed about their suicidal ideation at least once with someone. Nearly 7.5% ($n = 29$) of the students reported that they are likely to have future thoughts of attempting suicide.

Table 3 shows that the association between year of the study and PHQ scores was highly significant ($P < 0.001$). Most of the 3rd-year BDS and 1st-year MDS students (33.3% and 54.2%, respectively) were having minimal depressive symptoms. The number of 4th-year BDS students with both minimal and moderate depression with mild severity was equal. Interns and 2nd-year postgraduates were within normal range or full remission. Third-year postgraduates were having major depression with mild severity. The association of PHQ-9 scores and gender shows that 15.2% of the female participants were with moderate and severe major depressive symptoms that warrant treatment. Nearly 22.4% of the male participants

were with moderate and severe major depressive symptoms that warrant treatment and this association showed statistical significance ($P < 0.001$).

Table 4 shows the relation between PHQ and SBQ where with one unit increase in PHQ score, there were 1.283 units of increase in SBQ score. 19% of the variance in SBQ was explained by PHQ alone.

Discussion

The present study reports that majority of the study participants were perceiving depression of various levels while most of the participants were with low to high level of suicidality, which was higher in a study done by Deeb *et al.*^[6] In the present study, the participants perceived higher PHQ-9 scores when compared to that of the study done by Deeb *et al.*^[6] and less when compared to that of the study conducted by Galan *et al.*^[13]

PHQ instrument also includes a functional health assessment. This extracts the information regarding emotional difficulties or problems that impact work, things at home, or relationships with other people. Patient responses can be one of the following four: not difficult at all, somewhat difficult, very difficult, and extremely difficult. The last two responses suggest impaired functionality. Whereas in the present study, certain percentage of the students were with impaired functionality and needed compulsory treatment.^[11]

The participants had a plan of killing themselves at least once and even had attempted to kill themselves. This gives an alarming sign that reflects their failure to manage stress. While the study participants had the thought of attempting suicide in the past year at least once, similar results were observed in a survey done by Galan *et al.*^[13]

Table 1: Distribution of study participants according to their level of depression severity (Patient Health Questionnaire-9 scores) and perceived difficulty of the problems faced by the participants (functional health assessment)

	Frequency (%)
Level of depression severity (PHQ-9 scores)	
0-4 (minimal)	98 (25.3)
5-9 (mild)	129 (33.0)
10-14 (moderate)	96 (24.7)
15-19 (moderately severe)	43 (11.1)
≥20 (severe)	22 (5.9)
Total	388 (100)
Perceived difficulty of the problems faced by the participants (functional health assessment)	
No difficult at all	128 (33.0)
Somewhat difficult	218 (56.2)
Very difficult	34 (8.8)
Extremely difficult	8 (2.1)
Total	388 (100)

PHQ=Patient Health Questionnaire

Table 2: Frequency distribution for various questions in the Suicidal Behaviours Questionnaire

Questions	n (%)
SBQ-1. Have you ever thought or attempted to kill yourself?	
Never	249 (64.2)
It was just a brief passing thought	77 (19.8)
I have had a plan at least once to kill myself but did not try to do it	37 (9.5)
I have had a plan at least once to kill myself and really wanted to do it	12 (3.1)
I have attempted to kill myself, but did not want to die	3 (0.8)
I have attempted to kill myself, and really hoped to die	10 (2.6)
Total	388 (100)
SBQ-2. How often have you thought about killing yourself in the past year?	
Never	268 (69.1)
Rarely (1 time)	70 (18.0)
Sometimes (2 times)	26 (6.7)
Often (3-4 times)	13 (3.4)
Very often (5 or more times)	11 (2.8)
Total	388 (100)
SBQ-3. Have you ever told someone that you were going to commit suicide, or that you might do it?	
Never	76 (54.6)
Yes, at one time, but did not really wanted to die	29 (20.8)
Yes, at one time and really wanted to die	18 (12.9)
Yes, more than once, but did not want to do it	7 (5.03)
Yes, more than once, and really wanted to do it	9 (6.4)
Total (students at least with the thought of suicide)	139 (100)
SBQ-4. How likely is it that you will attempt suicide someday?	
Never	306 (78.9)
Unlikely	53 (13.7)
Likely	19 (4.9)
Very likely	10 (2.6)
Total	388 (100)

With suicidal thoughts, the participants had discussed about their suicidal ideation with others at least once, whereas half of them were not sharing with anyone, which

is not a good indicator for prevention. For a segment of the participants, it was likely to get a thought of suicide in future, which is an alarming sign. Final-year postgraduate students were having major depression with mild severity. The reason could be academic pressure as they have to clear university examinations. All these findings indicate failure of students in managing stress.

The link between suicide and depression is well established in high-income countries; many suicides

happen impulsively in moments of crisis with a breakdown in the ability to deal with life stresses. Stress describes external demands (physical and mental) on an individual's physical and psychological well-being. Although it has been hypothesized that some stress may actually be beneficial as a stimulus for learning, the negative consequences of stress are significant which progress sometimes to depression and tend to initiate suicidal ideation. Although various situations tend to elicit different patterns of stress responses, there are also individual differences in stress responses to the same situation. This tendency to exhibit a particular pattern of stress responses across a variety of stressors is referred to "response stereotypy."^[14] A study was done by Schmitter *et al.* to compare chronic stress between medical and dental students which concluded that chronic stress was more pronounced among dental students.^[15]

In this study, the PHQ scores were directly related to the SBQ scores, which suggests that students with depression were having high suicidal behavior. There was a statistically significant association between depression and suicidal behavior, which was similar to a study done by Galan *et al.*^[13] There was a statistically significant difference in PHQ scores between males and females, with females perceiving higher depression compared to males, which was in accordance with the study by Shetty *et al.*^[8] and in contrast to a study done by Galan *et al.*^[14] and Deep *et al.*^[6]

Case control studies can be done exploring the factors associated with suicidal behavior. Early identification; treatment; and care of people with mental disorders, substance use disorders, chronic pain and acute emotional distress can prevent suicides. While training of non specialized health workers in the assessment and management of suicidal behavior; follow up care for people who attempted suicide; and provision of community support are needed.

Limitation and recommendation

Limitations

Because it is a cross-sectional self-reported survey, no causal relationship can be determined and as the study was done in one institution, the results cannot be generalized. The cross-sectional nature of the study, the possibility of retrospective bias especially in the aftermath of the suicidal attempt, and lack of scales for assessing psychiatric morbidity (especially depression and stressors) are limiting our results.

Recommendation

Suicides are preventable, and there are a number of measures that can be taken at population, sub-population, and individual degrees to save an individual from committing suicide. Preventable measures such as by

reducing ingress to the means of suicide (e.g., pesticides, firearms, and certain medications); by reporting through media in a legitimate responsible way; and by introducing alcohol notions to reduce the harmful intake of alcohol are also important.

Suicide is a complex issue, and therefore suicidal prevention efforts require coordination and collaboration among multiple sectors of the society. Suicides come into limelight only when people with celebrity status commits it, therefore governmental efforts must be comprehensive and integrated as no single approach alone can make an impact on an issue as complex as suicide.

Many nongovernmental organizations are providing toll free numbers, hence it is essential for all of us as a society to frame a safe network for people going through arduous times and be prepared to listen and remind them of their ingenuity while it is high time that the government should concentrate on mental health issues and provide the toll free number that might help individuals with suicidal thoughts and at the same time bring a policy that every educational institution should have a team to monitor such acts.

Conclusion

As depression and suicidal tendencies are very prominent in students nowadays especially dental students, there is a need to shed light on these and take necessary reforms to relieve academic stress. The current investigation uncovered a wide scope of causative variables of self-destruction among dental understudies which is because of a progression of academical pressures, future settlement, and finance.

Abstract

Introduction: There is a possibility that the coronavirus disease (COVID-19)-related anxiety may differ between people from varied socioeconomic status for a variety of reasons. Furthermore, the adherence to COVID-19 precautionary measures could be different between socioeconomic strata in light of the differences in opportunities to more effectively follow these measures for people from different socioeconomic status. **Aim and Objectives:** The aim of this study was to check the differences in COVID-19 anxiety and precautionary measure adherence between subjects from different socioeconomic strata and to conduct a stratified analysis of the association between anxiety and adherence based on socioeconomic status of the participants. **Materials and Methods:** This longitudinal study was conducted in the months of July and November 2020 among 648 subjects belonging to the coastal districts of Andhra Pradesh. The COVID-19 Anxiety Scale (CAS) was used to assess the disease-related anxiety among the study participants, and self-reported adherence (SRA) scores were collected to document the adherence of the study subjects to COVID-19 precautionary measures. Statistical analysis was performed using SPSS version 20 software. **Results:** Significant differences were found in the CAS scores between subjects from different socioeconomic strata in the month of July, while no such observations were made in November. For the outcome of SRA scores, there were significant differences between socioeconomic strata at both the study time points. Overall, the mean CAS and SRA scores decreased from July (20.35 ± 5.54 and 14.48 ± 3.45 , respectively) to November (15.96 ± 5.67 and 12.57 ± 4.17 , respectively). **Conclusion:** The study results highlight the need to reinforce the necessity and importance of adhering to COVID-19 precautionary measures in light of the potential danger of the second wave of COVID-19 in the country.

Keywords: Compliance, COVID-19 anxiety, health behaviors, socioeconomic status

INTRODUCTION

Coronavirus disease (COVID-19) has been one of the largest pandemics the world has witnessed in the recent years. Worldwide, 42.3 million people were affected by the disease by the middle of December 2020. There have been 1.66 million COVID-19 deaths globally, and new disease-specific deaths have been adding to the tally every day. The number of COVID-19 cases in India accounted for 13.3% of the global burden of the disease, and the disease-specific deaths in India were 8.67% of the global COVID-19 deaths. The recovery rate in India is substantially higher at 95.2% compared to the

global recovery rate of 56.4%.^[1] It has widely been established that COVID-19 has a significant impact on the mental health of people.^[2-4] Besides the fear of infection, there has been enormous economic pressure on populations.^[5] At this juncture, it is imperative to refer to the fact that there is no specific treatment available for COVID-19, and the medical support

offered is predominantly symptom based. Many nations across the globe have been relying on practice of precautionary measures and imposing nonpharmaceutical interventions such as lockdown to combat the spread of the disease.^[6] There has been a stronger emphasis on promotion of the importance of practicing precautionary measures to prevent COVID-19 ever since the initial outbreak of COVID-19. In India, this campaign was endorsed by noted people from different professions such as cinema, sports, and politics. Aarogya Setu, a mobile app developed by the Government of India, utilizes contact tracing in identification of information relating to people, the users of the app might have contacted. In case any of these people tests positive for COVID-19 in future, the app instantaneously conveys the information to the users and arranges for medical care.^[7] However, it is obvious that not everyone gets an equal opportunity to practice the suggested precautionary measures. While most cases of nonadherence are circumstances driven, there is a possibility that the perceived severity of the pandemic and the associated disease-related anxiety at an individual level would influence the adherence of individuals to precautionary measures suggested. Moreover, it is understandable that socioeconomic status of a person can influence the adherence to precautionary measures and may also influence the anxiety levels of the subjects.^[8] Till date, there were no studies conducted in India which evaluated the differences in COVID-19 anxiety and adherence to COVID-19 precautionary measures based on socioeconomic status. Furthermore, the relationship between anxiety and adherence in a stratified analysis based on socioeconomic status has not been explored. With this background, the aim of this study was to check the differences in COVID-19 anxiety and precautionary measure adherence between subjects from different socioeconomic strata and to conduct a stratified analysis of the association between anxiety and adherence based on socioeconomic status of the participants.

MATERIALS AND METHODS

This longitudinal study was conducted from July 2020 to November 2020 among 648 subjects aged 18 years and older regardless of gender. Data were collected on two occasions from the same panel of participants in the months of July and November. This study was conducted in the coastal districts of Andhra Pradesh using a stratified systematic random sampling. All the participants were informed about the nature and purpose of the study, and written informed consent was obtained. The ethical approval of the study was obtained from the institutional review board (14/20/IRB/SBDC) on June 23, 2020. Sample size was calculated to be 449 using G*Power 3.1.9.2 software (Dusseldorf University, Germany). Based on the longitudinal nature of the study, a sample size of 650 was considered in the study.

A thorough review of literature was performed to identify the validated psychometric tools which measure the COVID-19 anxiety.^[9-15] Of all the scales assessed, the COVID-19 Anxiety Scale (CAS) developed among the Telugu-speaking population

of the state of Andhra Pradesh was deemed relevant. CAS is a seven-item scale on a four-point semantic differential scale with overall scale scores ranging from 7 to 28.^[12] To measure the adherence of the study participants to COVID-19 precautionary measures, an interviewer-administered structured questionnaire with three questions rated on a six-point Likert scale was used. The three questions included in the questionnaire were the adherence to precautionary measures suggested to prevent the spread of COVID-19: use of face mask, frequent handwashing, and maintaining social distance. The score obtained by a participant in the adherence questionnaire is identified as the self-reported adherence (SRA) score and ranges from 3 to 18, with higher scores indicative of better adherence. Demographic details of the study participants such as age, gender, and socioeconomic status were also documented. Socioeconomic status of the participants was recorded using the modified BG Prasad scale updated in 2020 based on the per-capita monthly income.^[16] Since there were a very less number of participants in the lower and upper socioeconomic strata, subjects belonging to these strata were combined with subjects from lower-middle and upper-middle socioeconomic strata, respectively. There was a loss of 77 subjects to follow-up, and only 571 subjects were assessed for COVID-19 anxiety and adherence to precautionary measures during the follow-up in November. Figure 1 presents the study flowchart. Statistical analysis was performed using SPSS version 20 software (IBM SPSS Statistics for Windows version 20, Armonk, NY, USA). Descriptive statistics, one-way analysis of variance with Tukey's *post hoc* tests, paired *t*-tests, and Spearman's correlation tests were used in data analysis.

RESULTS

The mean age of the study participants was 47.54 ± 8.9 . There were no significant age differences between subjects from different socioeconomic strata. The mean CAS score was 20.35 ± 5.54 in the month of July which decreased to 15.96 ± 5.67 in the month of November. Similarly, mean SRA scores dropped from 14.48 ± 3.45 to 12.57 ± 4.17 during this time. Significant differences were found in the CAS scores between subjects from different socioeconomic strata in the month of July, while no such observations were made in November [Table 1 and Figure 2]. For the outcome of SRA scores, there were significant differences between socioeconomic strata at both the study time points. *Post hoc* tests revealed similar CAS scores in the month of July between subjects from middle and upper-middle, upper socioeconomic strata [Table 2]. The middle and upper-middle, upper socioeconomic strata demonstrated similar SRA scores as well in the month of November. Table 3 shows that in each socioeconomic stratum, there was a significant decline in the mean CAS scores and mean SRA scores from July to November. There was a significant strong positive correlation between CAS and SRA scores in upper, upper-middle socioeconomic strata (Spearman's $\rho = 0.69$; $p = 0.001^*$). A significant weak positive correlation was observed between

these two parameters in the middle, lower-middle, and lower socioeconomic strata at any of the study time points

substantial decline in the COVID-19 anxiety levels of the population and also people's adherence to COVID-19 precautionary measures over the course of this study. While a decrease in anxiety levels is anticipated in light of the consistently reducing number of COVID-19 cases detected per day and the decreasing COVID-19 case fatality rates,

DISCUSSION

It is clearly evident from this study there has been a

Table 1: Differences in COVID-19 Anxiety Scale and self-reported adherence scores based on socioeconomic status

Time	Parameter	Socioeconomic status	n	Mean ± SD	95% CI for mean	P
July	CAS	Lower and lower middle	220	18.76±5.55	18.02–19.5	0.001*

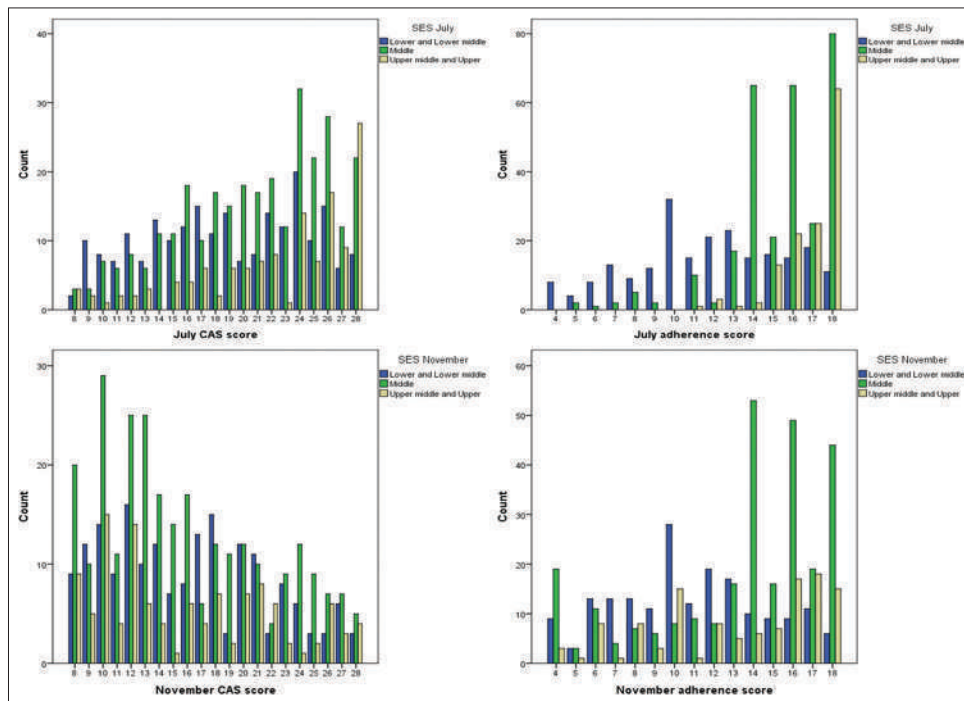

Figure 2: Clustered bar charts showing differences in COVID-19 Anxiety Scale and self-reported adherence scores between socioeconomic strata at the two study time points

poor adherence to precautionary measures is unwarranted. An area of significant concern is the difference in SRA scores between subjects from different socioeconomic strata. This observation persisted throughout the course of this study, the reasons for which could be found in the limited opportunities in adherence to precautionary measures for people from low socioeconomic strata possibly living in relatively overcrowded places and working in environments which are not conducive to the practice of social distancing. Furthermore, frequent handwashing and use of masks may not be financially feasible for this population resulting in poor SRA scores. Another significant area of concern is the magnitude of reduction in the adherence to COVID-19 precautionary measures among subjects from upper and upper-middle socioeconomic strata. A significant reduction in COVID-19 anxiety scores among these people could have contributed toward decreased adherence scores among

these people in light of the strong positive correlation between CAS and SRA scores in the upper and upper-middle socioeconomic strata.

The results from this study were observed to be consistent with the results reported by Bazaid *et al.* in Saudi Arabia where increased adherence to precautionary measures was observed among participants with high socioeconomic status.^[17] Paykani *et al.* reported that socioeconomic status was not found to be associated with compliance to stay-at-home advice among Iranian adults.^[18] Nevertheless, it was observed that subjects who rated their social class to be relatively poor compared to others demonstrated limited compliance. Higher levels of anxiety were reported among subjects from higher socioeconomic strata in a study conducted by Salameh *et al.* in May 2020 in Lebanon which is consistent with the observations made in this study.^[19] In another study conducted

by Agberotimi *et al.*^[20] in Nigeria, in the months of March and April 2020, results inconsistent with this study were demonstrated with similar anxiety levels between subjects from different socioeconomic strata; however, there were significant differences in depressive symptoms with higher prevalence among lower socioeconomic strata.

Clark *et al.* reported that the feeling of vulnerability to COVID-19 had little influence on the subjects' compliance to precautionary measures among an international sample of 8317 people.^[21] Similar findings were observed in this study with a weak correlation between COVID-19 anxiety scores and the SRA to precautionary measures among subjects from lower, lower-middle, and middle socioeconomic strata. However, there was a strong positive correlation between anxiety and adherence to precautionary measures among the subjects from upper-middle and upper socioeconomic strata. Chandu *et al.* reported limited adherence to COVID-19 precautionary measures among a student population in India.^[22] While there were no studies in India which directly assessed the influence of socioeconomic status on the adherence to COVID-19 precautionary measures, it was identified from an Indian study that educational level, an integral component of socioeconomic status, of the subject is an important predictor for adherence to precautionary measures.^[23] Wong *et al.* reported that increase in COVID-19 anxiety between two given time points was a significant predictor for increase in adherence to precautionary measures between those two time points.^[24] This observation was similar to that made in this study among subjects from higher socioeconomic strata. Outside the COVID-19 context, a relation between anxiety and adherence was thoroughly explored. People with any severity of anxiety demonstrated reduced adherence to antihypertensive medication in a study conducted by Bautista *et al.* in 2012.^[25] Similar results were reported by Sundbom and Bingeors in 2013 where nonadherence was more common among those prescription drug users who were identified to have symptoms of anxiety.^[26] Gaining insights into the differential manifestation of COVID-19 anxiety among people belonging to different socioeconomic strata is important in the identification of people who require mental health services. The results observed in this study contribute to the primary care provision by population-level identification of the differing COVID-19 anxiety levels based on socioeconomic status which helps not only in preparing the health-care delivery systems for the provision of required mental health services but also enables the administrative authorities to focus on the reasons for the emergence of COVID-19 anxiety as a function of socioeconomic status. The limitations of this study include a substantial loss to follow-up and lack of information on the reasons for the dropout. Moreover, the study did not collect information on the COVID-19 infection status of the participants and their family members which could have a direct influence on both the outcome parameters of anxiety and adherence. The study findings of decreased SRA to COVID-19 precautionary measures from July to November 2020 highlight

the need to reinforce the necessity and importance of adhering to COVID-19 precautionary measures in light of the potential danger of the second wave of COVID-19 in the country. Furthermore, people from lower socioeconomic strata must be provided with enough opportunities to more effectively practice the suggested precautionary measures. There is also a need to restructure the campaigns from delivering information to showing directions on how to effectively practice the precautionary measures.

CONCLUSION

Within the limitations of this study, the difference in COVID-19 anxiety scores was observed based on socioeconomic status at the beginning of the study, with people from lower socioeconomic status demonstrating the least anxiety. There had been a decline both in the COVID-19 anxiety scores and the SRA to COVID appropriate behavior with time.

ABSTRACT

Aim: To assess the awareness of clinical dental students regarding medical emergencies encountered in dental practice and their perceived confidence in managing them.

Materials and Methods: A cross-sectional study was conducted among 217 dental students with a pretested validated questionnaire consisting of questions pertaining to knowledge, attitude and their confidence in handling medical emergencies. Data collected was statistically analyzed by using SPSS version.20.

Results: Out of 217 study subjects, 187 returned completed questionnaires with response rate of 86%. 99.5% study subjects felt that taking medical history is useful in designing treatment plan. 81.3% said that syncope was the most commonly seen dental emergency during dental practice.

Conclusion: Handling of medical emergencies should be taught early from 3rd year as that could help them to retain the knowledge of basic sciences from the preclinical years and apply them in their practice during their clinical years.

Keywords: Dental students, knowledge, medical emergency, preparedness

INTRODUCTION

There are too many causes in the dental office which may provoke medical emergencies. Common causes of emergency cases include the frequent administration of local anaesthetics and other medications, the use of dental materials with high sensitizing potential, the attention of medically compromised patients and adult patients, the anxiety of uncertain surgical procedures in many patients.¹³

Generally, by taking a detailed medical history, assessing the patient and formulating a structured treatment plan with necessary improvements to dental care if needed, a medical emergency may be prevented.^{8,12} Lack of training and inability to cope with medical emergencies can lead to tragic consequences and sometimes legal action. Therefore, dental professionals should be able to properly understand and communicate with relevant health conditions, as well as have sufficient knowledge of oral health treatment and possible interactions with medical conditions.⁸

In dental profession, unexpected medical emergencies might happen and can be life-threatening in certain instances. Negative reactions to local anaesthesia, syncope, epileptic

seizures, hypoglycemia and angina pectoris, both of which have the ability to be life-threatening, are the most frequent medical complications in the dental clinic.⁹ To prevent morbidity and death, the dentist should be able to initiate primary care, and this warrants the need for basic information and material preparedness to recognize, access and handle emergencies in one's practice.^{9,10} So, with this background the current study was done to assess the awareness of clinical dental students regarding medical emergencies encountered in dental practice and their perceived confidence in managing them.

MATERIALS AND METHODS

A cross-sectional study was conducted in a dental college among 217 dental students who are posted in clinical practice were given a pre-tested validated self-administered questionnaire consisting of questions about knowledge, attitude and confidence in handling medical emergencies. Students who are present during the study period and those who returned the completed questionnaires are included in the study. Ethical approval was taken from the institutional ethical committee (IEC) prior to the commencement of

the study. The questionnaire consisted mainly of objective questions, and informed consent was taken prior from all the study participants. Reliability of the questionnaire was determined by using Cronbach's alpha coefficient test, which gave a value of 0.76. Data thus obtained were entered into Excel sheet and analyzed by using Statistical Package for Social Sciences (SPSS) version.20 whilst Descriptives and Chi-square test were done where p value ≤ 0.05 is considered as statistically significant.

RESULTS

Out of 217 study subjects, 187 returned completed questionnaires with a response rate of 86%. While 99.5% of study subjects felt that taking a medical history is useful in designing the treatment plan. 155 students felt that exposure to previous dental treatment will reduce the incidence of a medical emergency. The majority of the participants said that anxiety is the common cause of the medical emergency.

81.3% said that syncope was the most commonly seen dental emergency during dental practice, of which 44(72.1%) third BDS, 81(83.5%) fourth BDS, and 27(93.1%) interns. 82.8% of interns, 80.4% of fourth BDS and 54.1% of third BDS students are aware of emergency drugs and the kit to be available in the dental office, which is statistically significant. 86.2% of interns underwent BLS training when compared with fourth and third BDS students, which is statistically significant.

The majority of the students from 93.8% final and 93.1% interns said BLS training is required, which is statistically significant. More than half of the study participants are not confident in handling a medical emergency situation.

DISCUSSION

Although, the life-threatening emergencies in the dental offices was infrequent, many factors can escalate the likelihood of such events which include an increasing number of older persons seeking dental care, therapeutic advances in dentistry, longer appointments and increased drug usage. A medical emergency may arise on the dental chair despite efforts to minimize them. Lack of training and inability to cope with these can lead to tragic consequences.

In the present study, 94% of the students told recording medical history is useful in designing a treatment plan, which is similar to a study conducted by Alsahrani.F (2017)³ 85% of the students thought recording medical history is useful in designing a treatment plan. 64% of students in the present study are aware of the BLS technique, while in the study done by Ibrahim Aliyu et al⁷ 73.3% are aware, which was in

contrast to the study done by Neha Baduni.N (2014)⁸ where none of the participants had complete knowledge about BLS. In this study, 72% of students were aware of the emergency kit which is; in contrast, to a study conducted by Alsahrani.F (2017)³ where 60% of students were aware of emergency kit which is to be available in the dental office.

49% of students in the present study were confident to handle the emergency situation, which is similar to the study done by Aadil Ahamed (2016)¹ and Sharma P (2019)¹¹ and which was seen different results from a study conducted by Fasoyiro.O (2019)⁶ where 72% of students were competent enough to handle an emergency situation.

On analyzing the results fourth BDS students and interns were more aware of emergency situations and the way to handle them when compared to third BDS students whilst fourth BDS students had almost equal levels of knowledge as interns. This could be because of guest lecture regarding medical emergencies, the fourth BDS students had before the day of the survey

In the present study, 81% observed syncope as most common medical emergency, which is similar to the study conducted by Sheikho.M.A (2018)¹², in his study most common medical emergency was vasovagal syncope and second most common medical emergency was hypoglycemia, which is, in contrast, to study done by Elanchezhiyan.S (2013)⁵, were 43% reported that syncope is the commonest medical emergency in dental office.

In the present study 69% of the participants said anxiety is the common cause for a medical emergency, which is similar to the study done by Elanchezhiyan.S (2013).⁵ In this study, 81% agreed to check vital signs before to dental treatment, which is less when compared to study by Sheikho.M.A (2018)¹² 97.3% of the respondents check the vital signs prior to dental extraction.

Nearly half of the participants experienced at least one emergency situation. In a study conducted by Sharma P (2019)¹¹ 29.4% of them obtained vital signs before commencing any treatment.

In this study, nearly 78% of participants said that BLS training is necessary to everyone, but only 64.2% of dental students are trained in BLS, which is in contrast to the study done by Elanchezhiyan.S (2013)⁵ even though 96% reported that the BLS course is mandatory for dentists, only 56% said they had trained in BLS, and which is similar to the study done by Joshi.S (2016).¹³ In present study only 69% responded

Dr. L. KRISHNA PRASAD
DEAN
SIBAR INSTITUTE OF DENTAL SCIENCES
GUNTUR-522509, A.P., India.

that patient anxiety is the common cause for medical emergencies.

In the present study 83% of the students felt recording medical history plays a vital role in medical emergency management, which is similar to the study conducted by Elanchezhiyan.S (2013)⁵ 100% agreed that medical history plays a vital role in emergency management. Analysis of the study showed that awareness level of students was not satisfactory and special gridlines are required to enlighten the students regarding medical emergencies encountered in dental practice and handling them efficiently

As Goldberger said in the year 1990, that the emergency ceases to exist as you prepare for an emergency. So, for the worst case, we need to be prepared.

CONCLUSION

The observation of the survey showed that most of the participants were lacking confidence in handling medical emergencies. The study showed that there is finding a dearth of knowledge among dental students and interns in dealing with medical emergencies. Annual basic life support and emergency courses should be made mandatory in the dental teaching curriculum, and further hands-on training is required to update their knowledge to enhance their capability to recognize and manage a medical emergency and to become well-qualified practitioners.

Abstract

Introduction: The effect of N95 respirators for the protection against the infection is still undetermined. Hence in this study we evaluated the effectiveness of N95 respirators against surgical masks for inhibition of SARS- COV2 by gathering randomized controlled trials (RCTs).

Materials and Methods: Online data from PubMed, EMBASE, Cochrane Library was searched for period of one year from Jan-2020 to jan-2021. The studies between 2009 and 2020 were searched. The systematic reviews were considered. The RCTs incorporated in systematic reviews were recognized. We also searched for the RCTs done independently. Risk of the bias was evaluated by 2 reviewers independently after data extracted. Meta-analyses were done to calculate pooled estimates by RevMan 5.3 software.

Results: A total of six RCTs involving 9171 participants were included. There were no statistically significant differences in inhibiting laboratory-confirmed SARS- COV2 (RR = 1.09, 95% CI 0.92- 1.28, P > .05), laboratory-confirmed respiratory viral infections (RR = 0.89, 95% CI 0.70-1.11), laboratory-confirmed respiratory infection (RR = 0.74, 95% CI 0.42-1.29) and influenza like illness (RR = 0.01, 95% CI 0.33-1.14) using N 95 respirators

and surgical masks. Meta-analysis indicated a protective effect of N95 respirators against laboratory-confirmed bacterial colonization (RR - 0.58, 95% CI 0.43-0.78).

Conclusion: The use of N95 respirators matched with surgical masks is not associated with a lower risk of laboratory-confirmed SARS- COV2. It suggests that N95 respirators should not be recommended for general public and non high-risk medical staff those are not in close contact with SARS- COV2 patients or suspected patients.

Keywords: Surgical masks, N95 respirator, Respiratory tract infections.

Introduction

Severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV) have mortality rates about 10% and 37%, correspondingly.¹ Ever since the outbreak of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), facemasks have been deliberated to be vitally important to reduce the risk of infection because vaccination or specific anti-infective treatments are unavailable.^{2,3} N95 respirators are used to protect users from inhaling small airborne particles and must fit tightly to the user's face. Surgical masks are intended to protect wearers from microorganism transmission and fit slackly to the user's face.^{5,6} Though surgical masks cannot stop inhalation of small airborne particles, both of them can defend users from large droplets and sprays.^{7,8} There are inconsistent recommendations for severe acute respiratory syndrome (SARS) and pandemic influenza: the World Health Organization (WHO) recommends using masks in low-risk situations and respirators in high-risk situations, but the Centers for Disease Control and Prevention (CDC) endorses using respirators in both low and high-risk situations.⁹ However, N95 respirators may play a incomplete role in low-resource settings, where there are a limited number of N95 respirators, or it may be too expensive.⁹ Also, previous meta-analyses determined there was insufficient evidence to determine the effect of N95 respirators due to a small number of studies that is prone to lack of statistical power.^{10,11} Furthermore, these meta-analyses were limited by the small number of included randomized control trials (RCTs). More, well planned RCTs of comparing N95 respirators with surgical masks against influenza published in recent years were not incorporated in previous meta-analyses.¹²⁻¹⁴ In light of the growing number of RCTs of masks use for protecting against, this systematic review and meta-analysis intended to evaluate the effectiveness of N95 respirators versus surgical masks for prevention of SARS- COV2.

Materials and method

This meta-analysis was piloted based on the preferred reporting items for systematic reviews and meta-analyses (PRISMA) guidelines.¹⁵ We included only the studies that were

- (1) RCT (including cluster randomized trial) and nonrandomized controlled study;
- (2) COVID patients
- (3) N95 respirators and surgical masks
- (4) RTPCR- confirmed cases only was taken as primary outcome variable
- (5) Other lab confirmed respiratory viral, bacterial infections are taken as secondary outcome variables
- (6) Hospital or community.

All the other human studies with improper design were excluded.

Search approach

Online data from PubMed, EMBASE, Cochrane Library was searched for period of one year from Jan-2020 to Jan-2021. The terms like N95 mask, surgical mask, SAR-COV2, systemic reviews, meta analysis. Later, primary RCTs included in the systematic reviews were identified. Furthermore, we piloted an additional search to identify RCTs published in the past five years from January 27, 2015, to January 27, 2020, using the databases and search strategies described above.

Data mining:

Two reviewers independently selected the articles based on the titles, abstracts and full texts. Then, two reviewers independently extracted the following data from included studies: first author, publication year, country, disease, details of study population and intervention, study design, sample size, settings, and results.

Risk of bias assessment

Two reviewers independently assessed the risk of bias of the selected RCTs using the Cochrane Risk of Bias tool,¹⁶ which includes domains on random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessors, incomplete outcome data, and selective reporting. For each RCT, every domain was judged among 3 levels: high risk, unclear risk, and low risk. Disagreements were resolved by discussion.

Data analysis

All statistical analyses were performed using Review Manager (RevMan) version 5.3. Comparable data from studies with similar interventions and outcomes were pooled using forest plots. Relative risk (RR) with 95% confidence intervals (CIs) for dichotomous data was used as the effect measure. Between-study heterogeneity was assessed using the I^2 for each pooled estimate.¹⁷ We adopted a random-effects model for heterogeneity $P < 0.10$. We performed a subgroup analysis based on the settings (hospital, community) due to the possibility of clinical heterogeneity. A sensitivity analysis was conducted to evaluate the robustness of the results by excluding individual studies for each forest plot. Funnel plots were planned to assess publication bias. Because of the small number of studies available for each pooled estimate, we failed to assess publication bias.

Results

Search results and study characteristics

In total, we included six RCTs (12,18-22) and found no unpublished data of RCTs from ClinicalTrials.gov. The characteristics of these RCTs were presented in Table 1. The included studies published between 2009 and 2019. A total of 9171 participants in Canada, Australia, China, or America were included, and the number of participants in each RCT ranged from 435 to 5180 patients. The follow-up duration varied from 2 to 15 weeks. Five studies included participants in hospitals,^{12,18,20-22} and one in households.¹⁹ Because of different definitions of outcome in included studies, we redefined the laboratory confirmed respiratory infection as respiratory SARS- COV2, other viruses or bacteria infection. 3.2

Risk of bias

The results of the risk of bias assessment can be found in Figure 2. Five studies reported the computer-generated random sequences, while only one mentioned randomization. All studies did not mention allocation concealment. Participants and trial staff were not blinded in two studies, and the other two studies failed to mention the blinding of participants and personnel. Four studies did not report whether the outcome assessors were blinded. All studies had complete outcome data or described comparable numbers and reasons for withdrawal across groups and prespecified outcomes.

Effectiveness

Five RCTs involving 8444 participants reported laboratory-confirmed influenza &/ SARS-COV2.^{12,18-21} Meta-analysis with fixed-effects model revealed that there was no statistically significant differences in inhibiting influenza using N95 respirators and surgical masks (RR = 1.09, 95% CI 0.92-1.28, $P > .05$) (Figure 3). The results of subgroup analyses were consistent with this regardless of the hospital or the community. The results of the sensitivity analysis were not altered after excluding each trial. Four RCTs¹⁸⁻²¹ involving 3264 participants reported laboratory confirmed respiratory viral infections. Meta-analysis with fixed-effects model revealed that there were no statistically significant differences in inhibiting respiratory viral infections using N95 respirators and surgical masks (RR = 0.89, 95% CI 0.70-1.11, $P > .05$) (Figure 4). The results of subgroup analyses were consistent regardless of the hospital or the community. However, the sensitivity analysis after excluding the trial by Loeb et al¹⁸ showed a significant effect of N95 respirators on stopping respiratory viral infections (RR=0.61, 95% CI 0.39-0.98, $P < .05$). Two RCTs^{21,22} involving 2538 participants reported laboratory confirmed bacterial colonization. Meta-analysis with fixed-effects model revealed that compared with surgical masks, N95 respirators significantly decreased bacterial colonization in hospitals (RR = 0.58, 95% CI 0.43-0.78, $P < .05$) (Figure 5). The sensitivity analysis showed that the results did not change after excluding each trial. Two RCTs^{12,22} involving 6621 participants reported laboratory confirmed respiratory infection. Meta-analysis with random-effects model revealed that there were no statistically significant differences in inhibiting respiratory infection using N95 respirators and surgical masks in hospitals (RR = 0.74, 95% CI 0.42-1.29, $P > .05$) (Figure 6). However, the sensitivity analysis after excluding the trial by Radonovich et al¹² showed a significant effect of N95 respirators on inhibiting respiratory infection (RR = 0.53, 95% CI 0.35-0.82, $P < .05$). Five RCTs involving 8444 participants reported influenza like illness.^{12,18-21} Meta-analysis with random-effects model revealed that there were no statistically significant differences in inhibiting influenza like illness using N95 respirators and surgical masks (RR = 0.61, 95% CI 0.33-1.14, $P > .05$) (Figure 7). The results of subgroup analyses indicated that statistically significant superiority of N95 respirators over surgical masks against influenza like illness (RR = 0.37, 95% CI 0.20-0.71, $P < .05$) in the community (only one RCT). The sensitivity analysis showed results remained unchanged after excluding each trial.

Discussion

This meta-analysis showed that there were no statistically significant differences in inhibiting laboratory-confirmed SARS-COV2, laboratory confirmed respiratory viral infections, laboratory-confirmed respiratory infection and influenza-like illness using N95 respirators and surgical masks. N95 respirators delivered a protective effect against laboratory-confirmed bacterial colonization. In subgroup analysis, similar results could be found in the hospital and community for laboratory-confirmed influenza/ SARS- COV2 and laboratory-confirmed respiratory viral infections. Nonetheless, sensitivity analysis showed unstable results for the prevention of laboratory-confirmed respiratory viral infections and laboratory-confirmed respiratory infection. Over the course of influenza/ SARS- COV2 pandemics, large numbers of facemasks may be required to use in long periods to guard people from infections.²³ Using N95 respirators is probable to result in discomfort, for instance, headaches.²³ A earlier study³ reported that there was an converse relationship between the level of defiance with wearing an N95 respirator and the risk of clinical respiratory illness. It is problematic to ensure high compliance due to this discomfort of N95 respirators in all studies. The reason for the similar effects on inhibiting influenza/ SARS- COV2 for the use of N95 respirators versus surgical masks may be connected to low compliance to N95 respirators wear,²³ which may lead to more common doffing compared with surgical masks.¹³ Though N95 respirators may confer more protection in laboratory studies designing to achieve 100% intervention adherence,²⁴ the routine use of N95 respirators seems to be less acceptable due to more substantial discomfort in real-world practice.¹¹ Consequently, the benefit of N95 respirators of fitting tightly to faces is offset or subjugated.¹³ Nevertheless, it should be noted that the surgical masks are primarily designed to protect the environment from the wearer, whereas the respirators are supposed to protect the wearer from the environment.²⁵ There are some limitations to this study. First, some RCTs had a great risk of bias due to lack of allocation concealment and blinding; though it is impractical to blind participants who would know the type of masks they are wearing. Second, the number of comprised studies focusing on the community was small. Thus, the results of the subgroup analysis might be unreliable. Third, we identified RCTs from published systematic reviews, which may end in the omission of relative RCTs. Finally, there might be publication bias, and we cannot measure it due to an insufficient number of included RCTs.

Conclusion

In conclusion, the present meta-analysis shows the use of N95 respirators equated with surgical masks is not related with a lower risk of laboratory-confirmed influenza/ SARS-COV2. It proposes that N95 respirators should not be endorsed for the general public and non-high risk medical staffs those are not in close interaction with influenza/ SARS- COV2 patients or suspected patients.

Is the Profession of Dentistry Losing its Yesteryear's Glory? An Exploratory Study from Dental Students' Perspective

Abstract

Introduction: The regard for dentistry as a profession has been declining over the recent years in light of the increasing number of dental students graduating per year with negligible improvement in the utilization of oral health care services. In this context, it is important to document the perceptions and apprehensions of the current dental students as these feelings would have an influence on the roles they assume as dentists in future. **Aim:** With this background, this study attempts to document the willingness of dental students from three South Indian states to re-choose dentistry given an opportunity. **Materials and Methods:** This cross-sectional survey was conducted among house surgeons from 12 dental institutions, 4 each from the southern Indian states of Andhra Pradesh, Telangana, and Tamilnadu. The semi-structured questionnaire used in this study consisted of five primary questions along with details on the participants' gender, type of admission. It aimed at documenting the willingness to re-choose dentistry given an opportunity, and the reasons for their willingness or otherwise. A total of 822 students constituted the final sample. SPSS version 20 software was used to analyse the data. **Results:** Majority of the study participants were from Tamil Nadu, not reported dentistry as their primary career choice, and demonstrated reluctance in re-choosing dentistry given an opportunity. A significantly higher percentage of dental students from Tamil Nadu reported dentistry as their first professional choice. This observation persisted in the response of students for the question on their willingness to re-choose dentistry. **Conclusion:** The study results demonstrate the declining interest and regard for dentistry among the current dental students with nominal variations between students from the three South Indian states.

Keywords: Dental, dentistry, education, qualitative research

Introduction

Though dentistry is regarded as one of the oldest medical disciplines dating back to 7000 B.C., it is only over the last century that this discipline in health care got streamlined into a definite profession.^[1] In the Indian context, refinement of dentistry as a profession became possible with the inception of formal dental education. The first dental college in India was established in 1920 by Dr. Rafiuddin Ahmed in Kolkata.^[2] Since then the profession has evolved by leaps and bounds becoming one of the most sought after professions in the country. There has been a consistent increase in the number of dental colleges in India over the years with a pronounced increase seen during 1998 – 2014.^[3] At present, there are 315 dental educational institutions in India producing nearly 31,000 dental graduates every year, making India the largest producer of dentists across the world.^[4] However, this increase in the number of dental institutions in the country was not

demand-driven and neither was this choice methodically informed. Once the supply component in dental care delivery began to outstrip the demand component, the delivery systems started suffering from a reduced number of care seekers which consequently had given rise to a notion that dentistry as a profession is not fruitful anymore, at least not as yielding as it once was. The success of any profession is a complex interplay of a multitude of factors among which financial returns in the profession and societal regard for the profession could be considered the most determining. It is this reduction in societal regard for the profession and the reduced financial returns that prompted the aforementioned notion on the profession of dentistry.

Indian medical education system is an intricate organization with academic merit being not the only factor that warrants admission. While the distinction of this system is largely debated, from the educational institutions' perspective this mechanism ensures full

Quick Response Code:

enrollment. On the other side, the mechanism also offers solutions for parents of those students who demonstrated insufficient standards in the entrance examination, to choose a profession of their choice. It is under these circumstances that dentistry enjoyed almost full enrollment throughout the country despite an enormous increase in the number of dental institutions. However, the scenario has apparently been changing. There has been a consistent and considerable decline in the number of undergraduate admissions in dentistry over the last few years.^[5,6] While there could be a number of reasons for this phenomenon, the experiences of current dental students with dentistry and their understanding of the future in dentistry cannot be ignored. In this context, this study attempts to gain insights into the perceptions of current house surgeons in various dental colleges in Southern India to inform policymakers on the prospective ways to streamline the profession, should there be a need.

Materials and Methods

This cross-sectional questionnaire study was conducted among house surgeons from 12 dental institutions, 4 each from the southern Indian states of Andhra Pradesh, Telangana and Tamilnadu. Two-stage cluster random sampling was done, where three states were selected in the first stage and four dental institutions from each of these states were randomly selected in the second stage. All the house surgeons from the selected dental institutions were invited to participate in the study. The primary investigator made a correspondence with the coordinators of this study at each of the 12 dental institutions to discuss the study protocol. The participation in this study is voluntary and consent was obtained from all the willing participants before the questionnaire was administered. The questionnaire was administered to the consented house surgeons among the twelve dental institutions considered in this study in April 2019. The semi-structured questionnaire used in this study was divided into four sections: whether dentistry was participant's first choice; the participant's reasons for choosing dentistry as a career; whether the participant is willing at the present time to choose dentistry if he/she was given an opportunity to re-choose; participant's reasons for their willingness or otherwise in re-choosing dentistry. Details regarding participants' gender and type of admission were collected. The questionnaire was assessed for content validity by four experts in the field of dental education and a pilot test was done among 25 students to evaluate the face validity of the questionnaire. Students who participated in the pilot study were not included in the final sample. Of the 967 students approached, 98 students opted not to participate in the study, while 47 students returned incomplete or partially filled questionnaires. The final sample consisted of 825 house surgeons from the twelve selected dental institutions in Southern India. Approval obtained on 16th February, 2018. SPSS version 20 software (IBM SPSS statistics for Windows version 20, Armonk, USA) was used to analyze the study data. Descriptive statistics, Chi-square

test were performed to check the association of participants' regard for dentistry with background characteristics and the geographical location of the institution, and to extract themes that determined participants' responses on the willingness to re-choose dentistry given an opportunity.

Results

Of the 825 study participants, 193 (23.39%) were males. Majority of the participants (36.37%) were dental students from Tamil Nadu, followed by 273 (33.09%) from the state of Andhra Pradesh, and 252 (30.54%) from Telangana. Only 18.06% of the students reported dentistry as their first professional choice. The most common reason for choosing dentistry was reported to be the inability to secure an admission in medicine. There was a statistically significant difference based on geographical location with regard to students' response to dentistry as their first professional choice [Table 1] and the reasons given for choosing dentistry [Table 2]. A significantly higher percentage of dental students from Tamil Nadu reported dentistry as their first professional choice. This observation persisted in the response of students for the question on their willingness to re-choose dentistry if they were given an opportunity [Table 1]. A total of 35% of participants from Tamil Nadu demonstrated willingness to re-choose dentistry, while only 12.3% of students from Telangana and 23.07% of students from Andhra Pradesh showed willingness to re-choose, given an opportunity. However, no significant differences were noted in the interest of students to advise dentistry as a professional choice for their friends based on the geographical location of the students [Table 1]. Not more than a quarter of the students from all the three states included in the study expressed interest in recommending dentistry as a career choice for their friends. The scope that the profession offers to make people smile was the major reason for students' willingness to re-choose dentistry [Figure 1], while mental stress was the most common reason for the unwillingness to re-choose dentistry. The other reasons for students' reluctance in re-choosing dentistry were financially non-profitable nature of the profession and physically demanding nature of the profession [Figure 2].

Discussion

It is beyond doubt that the profession of dentistry has made great strides over the years. There has been tremendous expansion of the dental education in India since 1998. During the period of 16 years from 1998 to 2014, 206 new dental institutions were established in the country which accounts for an increase by 215.9%.^[3] The reports on the quality of dental education and the students' viewpoints on the learning environment in dental institutions are not very encouraging.^[7] In these circumstances, the results of this study that the majority of students were reluctant in re-choosing dentistry and would not suggest dentistry as a professional choice for their friends are not surprising. One of the

Figure 1: The reasons reported by the students for their willingness to re-choose dentistry

Figure 2: The reasons reported by the students for their reluctance to re-choose dentistry

important basis for the observation of geographical variation in students' preferences relating to re-choosing dentistry could be found in the cultural and attitudinal differences between the students from different states in general. Another obvious reason was dentistry being the first career choice for considerably more students from Tamil Nadu compared to the states of Telangana and Andhra Pradesh, which highlights the inherent interest among students from Tamil Nadu towards the profession that could have prompted them to respond positively about re-choosing dentistry given an opportunity. The fact that less than a quarter of the students participated in this study were willing to recommend dentistry as a career choice for their friends is reflective of the skeptical nature of students regarding their future as dental health professionals and another reason could be to avoid further competition in an already competitive environment.

This study highlights the apprehension of dental students about their future roles as oral health care professionals.

The analogy of supply-demand consideration in marketing applies in this context. In the financial market, when the supply component exceeds the demand component, the prices of the products drop. Similarly, when the available dental manpower is more than what is required to meet the demand for oral care, the regard for the profession diminishes among prospective students as the financial returns from the existing demand for oral health care have to be shared among an ever-increasing supply component.^[8] A report on the available dental manpower in Tamil Nadu by Prabu *et al.* revealed that the dentist to population ratio in Tamil Nadu was 1: 3667 while the recommended ratio by the world health organization was 1:7500.^[9] These numbers in the states of Andhra Pradesh and Telangana would not be too different. Barring the discussion on the reasons for geographical disparities in the available dental manpower between rural and urban areas, the available manpower is clearly more than what is demanded from the public.

When the students were probed about the reasons for their reluctance to re-choose dentistry, financially non-profitable nature of the profession, its physically and mentally demanding nature emerged as the major reasons. These observations highlight the expectations students have about their future career roles. It was reported in the literature that the image of oral health care professionals in some parts of the world is associated with wealth and prestige.^[10] However, the current Indian dental students cannot associate their future careers with wealth and prestige, given the circumstances. Few students who demonstrated willingness to re-choose dentistry given an opportunity opined that the relatively inexpensive nature of dental education compared to medical education suits them, and some students felt that the profession has more scope abroad. In a study conducted in British University of Egypt in 2016, 73.3% of students expressed satisfaction about their career choice as a dental professional which is in contrast with the results of the present study.^[11] Societal reputation, financially profitable nature of the profession were reported to be the main reasons for choosing dentistry by the dental students of Damascus University, Syrian Arab Republic.^[12] These findings are in accordance with the thought process of the students in the current study who demonstrated reluctance in re-choosing dentistry because of these reasons. In a study conducted by Aguiar CM *et al.* among Pernambuco dental students in Brazil, dentistry was not the first career choice for only less than 15% of the students, which is in contrast with the observations made in the present study where dentistry was the first career choice for only 18.06% of the students.^[13] Halawany SH reported dentistry as the primary career choice among Saudi dental students in 2014.^[14] Similar to this study, in a study conducted among dental students in Bhopal, 22.6% of final-year students reported choosing dentistry out of their own interest.^[15] This is a reflection for the fact that the dental students in the present study lack extensive knowledge and realistic expectations about the careers they are assuming, but follow the path of least resistance in making their career choices.

Conclusion

The study results demonstrate the declining interest and regard for dentistry among the current dental students. Though slight geographic variations were observed between the students belonging to different states in their responses regarding dentistry being the first career choice, majority of students regardless of their geographical location, were reluctant to re-choose dentistry given an opportunity. These findings raise concerns about the future of the profession in the country that produces the largest number of dental graduates per annum in the world, and must receive careful attention from all the stakeholders.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have

given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Background: It is beyond doubt that the health care systems across the globe have been experiencing burdens of unprecedented magnitude in the coronavirus disease (COVID-19) era. However, no psychometric tools were validated in India to assess the impact of COVID-19 on the psychological well-being exclusively among health care workers, given their obvious risk for exposure. **Objectives:** This study was conducted to develop the first of its kind psychometric tool that measures the psychological burden posed by COVID-19 on Indian health care workers. **Materials and Methods:** One hundred and sixty-nine health care workers attending COVID-19 duties in four different states of India took part in the study. The initial scale designed was tested for face and content validity. Exploratory factor analysis using direct oblimin rotation with Kaiser normalization was employed to determine the factor structure. Differential item functioning (DIF) analysis with ordinal regression based on the type of COVID-19 facility at which the participant is serving, educational background was done for identification of item bias. **Results:** COVID-19 Psychological Burden Scale for Indian Health Care Workers (CPBS-IHCW), with 17 items loaded on four components, demonstrated good internal consistency reliability (Cronbach's Alpha 0.873). DIF revealed no item bias based on type of facility and educational background. Significant differences in CPBS-IHCW scores were noted between health care workers serving at different COVID-19 facilities and belonging to different educational backgrounds. **Conclusion:** CPBS-IHCW is a 17-item, rapidly administrable scale, demonstrating good internal consistency reliability, and temporal stability, which can be used in the assessment of psychological burden among health care professionals catering to the needs of the COVID-19 affected.

DOI: 10.4103/ipj.ipj_71_21

the globe. In this context, health care professionals as front-line workers embraced a multitude of roles at various levels such as community awareness building, laboratory sample collection, monitoring and supervision of suspect cases, and provision of requisite care for the confirmed COVID-19-positive cases. Literature on previous outbreaks underscores the negative impacts of assuming front-line duties on the mental health and psychological well-being of health care workers.^[3-5] It is estimated that the magnitude of anxiety and stress, depression levels, and suicidal inclinations would rise as a consequence of the psychological burden posed by COVID-19.^[6] The vulnerability of health care workers in developing psychological symptoms such as insomnia, depression, and anxiety has been discussed in the context of COVID-19.^[7,8] In this fight against the unanticipated COVID-19 pandemic, there are many factors contributing to the appearance of burn-out among health care workers such as working in high-risk areas for infection, availability of suitable personal protective equipment, long work hours to meet the escalating demand, staying away from families, increasing reports on health care professionals communicating the disease, and uncertainty about the future.^[7]

Safeguarding the health of health care workers is one of the fundamental responsibilities of any health care system, which includes psychological well-being. The WHO Department of Mental Health and Substance Use developed a series of messages aimed at diverse audiences to reinforce mental health and psychological well-being in these challenging times.^[9] In order to provide requisite mental health and psychological support for health care workers in need, it is important to assess the psychological burden among the individuals. Although there are a number of available psychometric scales that measure the impact of COVID-19 on mental health,^[10-15] to the best of our knowledge, there are no validated psychometric measures intended for health care professionals to assess the psychological burden posed by COVID-19 in the Indian context. With this background, the objective of this study was to develop a scale to measure COVID-19 imposed psychological burden among Indian health care workers (IHCW), henceforth referred to as COVID-19 Psychological Burden Scale for IHCW (CPBS-IHCW), and evaluate its psychometric properties.

MATERIALS AND METHODS

This study was conducted during July and September 2020 among health care professionals attending COVID-19 duties in the Indian states of Andhra Pradesh, Telangana, Madhya Pradesh, and Odisha. Ethical approval for this study was obtained from the Institutional Review

Board of Sibar Institute of Dental Sciences (244/Sibar/IEC/2020;17/5/2020). The Government of India has categorized COVID-19 dedicated facilities into three types: COVID Care Center (CCC); Dedicated COVID Health Center (DCHC); Dedicated COVID Hospital (DCH).^[16] In addition to these COVID-19 dedicated facilities, field surveillance, field supervision, laboratory sample collection teams were instituted by the health authorities. CCC offers services only for COVID-19 suspect cases having mild and very mild symptoms (fever/upper respiratory tract infection). At DCHC, services for all moderate COVID-19 suspect cases (pneumonia with no signs of severe disease; respiratory rate 15–30 cycles/min; SpO₂ 90%–94%) shall be offered, whereas DCH is primarily for the provision of comprehensive care to severe COVID-19 suspect cases (respiratory rate \geq 30 cycles/min; SpO₂ <90% in room air).^[16] This classification of patients based on the severity of symptoms can be found in the ‘algorithm for isolation of suspect/confirmed cases of COVID-19’ proposed by the Ministry of Health and Family Welfare, Government of India.^[16] The study sample constituted of a convenience sample of 169 health care professionals, from the disciplines of modern medicine, dentistry, and nursing, who were involved in COVID-19 duties at CCCs, DCHCs, and DCHs during July and September 2020. The administrative heads at the district level were approached to gain access to the eligible participants. The scale was administered to these participants online via their registered contact numbers. All the participants provided informed consent. The background characteristics of age, gender, educational background, and qualification were documented from the study participants. For convenience, the methodology adopted in this study was discussed under the following subheadings: (i) generation of item pool; (ii) assessment of content validity and face validity; (iii) evaluation of corrected item-total correlations (ITC) and internal consistency reliability; (iv) identification of factor structure and scale purification; (v) differential item functioning (DIF) analysis for estimating item bias; (vi) Establishment of the temporal stability of the scale.

1. Generation of item pool: Thorough review of literature, regarding factors linked with health care professionals’ fear of acquiring the disease and the sources of anxiety, preceded the generation of item pool.^[7,17] Independent reviews by the investigators resulted in the drafting of initial questionnaire with 18 items in English. All the items were designed to assess the psychological burden, associated with COVID-19, among health care workers on a four-point (1–4) semantic differential scale, where the estimating facet was clearly mentioned in the choices, with higher scores representing increased psychological burden

2. The assessment of content validity and face validity: The initial scale with 18 items in English was assessed by a six-member expert panel for content validity that comprised of three psychiatrists and three members from the departments of community medicine. The authors who articulated the initial scale were not a part of the expert panel. The expert panel rated the 18 items on a four-point scale: “quite relevant;” “highly relevant;” “moderately relevant;” “poorly/not relevant.” Seventeen items in the scale were rated to be either “quite relevant” or “highly relevant” by all the panel members, and the item that received “moderately relevant” or “poorly/not relevant” response from few of the panel members was removed from the scale after consensus building. The inter-rater agreement was measured with Intraclass Correlation Coefficient (ICC) (Two-way mixed model, mean of six raters, absolute agreement).^[18] The scale level ICC was 0.89 for the 17 item scale, which was pilot tested on 10 health care workers attending COVID-19 laboratory sample collection duties to assess the face validity of the questionnaire. Two items were rephrased after conduct of the debriefing interviews as semantic discrepancy was noted with 3 members, i.e., discrepancy between what the item intends to assess and what the respondents understood from the item
3. Evaluation of corrected ITC and internal consistency reliability: Corrected ITC to assess the correlation of each of the scale items with the total scale score were used for initial scale purification.^[19] Items demonstrating a corrected ITC of <0.3 were intended to be eliminated from the scale, as values below the cut-off indicate limited association of the corresponding item to the overall construct measured by the scale.^[20] Internal consistency reliability of the scale was measured using Cronbach’s alpha
4. Identification of factor structure and scale purification: Exploratory factor analysis (EFA) was employed to determine the factor structure. Direct oblimin rotation with Kaiser normalization was done and items with significant cross loadings across components, should there be any, were intended to be removed if the difference between loadings is <0.2^[21]
5. DIF analysis for estimating item bias: DIF was done to check item equivalence.^[22] A difference in item responses across different categories of a grouping variable (e.g. COVID-19 health care facility), while controlling for the underlying construct measure is suggestive of DIF. The total score obtained on the scale was considered the conditioning variable and the “interaction term” between the grouping variable and the conditioning variable was also used in DIF analysis to assess the presence of nonuniform DIF.

A significant increase in R^2 value (>0.02) from model 1, where the conditioning variable was the only covariate, to model 3, where the grouping variable and the “interaction term” were added to model, is suggestive of DIF^[22]

6. Establishment of temporal stability of the scale: Temporal stability of the instrument was evaluated by re-administering the scale to 25 health care workers 1 week after the initial administration. ICC (Two-way mixed effects model, single rater, absolute agreement) was used as a measure for the temporal stability of the scale.

Statistical analysis

SPSS version 20 software (IBM SPSS statistics for windows version 20, Armonk, NY, USA) was used to analyze the data. The following were employed in data analysis: descriptive statistics; EFA using direct oblimin rotation with Kaiser Normalization for determination of factor structure; DIF analysis with ordinal regression based on the type of COVID-19 health care facility the participant serves in and educational background of the participant for identification of item bias; Mann–Whitney test for determining gender variation in CPBS-IHCW scores; Kruskal–Wallis ANOVA, with *post hoc* Bonferroni-adjusted Mann–Whitney tests for multiple pairwise comparisons, for identifying differences in CPBS-IHCW scores based on the type of COVID-19 health care facility, educational background, and qualification. For DIF analysis, the difference in Nagelkerke R^2 values from the three models employed in DIF analysis was used to assess the magnitude of DIF.

RESULTS

Majority of the study participants were females with master’s degree in modern medicine. The mean age

Item 9: How afraid are you of dying from COVID-19?	1.69 (0.81)	1 (1)	0.6	0.862
Item 10: How satisfied are you with the training received in preparation for COVID-19 duties?	2.14 (0.8)	2 (0)	0.51	0.865
Item 11: How confident are you in fulfilling the COVID-19 related responsibilities delegated to you?	1.69 (0.71)	2 (1)	0.52	0.865
Item 12: How assured are you about the quality and comprehensiveness of COVID-19 related evidence that you have received?	2.08 (0.74)	2 (1)	0.32	0.872
Item 13: How frequently have you been thinking of not attending COVID-19 duties delegated to you because of pressure from family members or close acquaintances?	3.02 (0.89)	3 (2)	0.35	0.872
Item 14: How assured are you about receiving necessary support from the community in case you develop COVID-19 related symptoms?	2.88 (0.8)	3 (1)	0.31	0.873
Item 15: How worried are you about the wellbeing of your family when you are fulfilling the delegated COVID-19 responsibilities?	2.27 (0.9)	2 (1)	0.61	0.861
Item 16: How apprehensive are you that the family members of an infected person may resort to violence against you or the facility in which you serve?	2.18 (0.8)	2 (1)	0.52	0.865
Item 17: How satisfied are you with the current access you have to personal protective equipment?	2.18 (0.79)	2 (1)	0.51	0.865

*Depicts internal consistency estimates of remaining items if the corresponding item is removed from the total score. SD=Standard deviation, IQR=Interquartile range

of the study sample was 28.86 ± 6.38 years. Table 1 shows the background characteristics of the health care workers who participated in this study. All the 17 items of CPBS-IHCW demonstrated corrected ITC >0.3 (0.31–0.63). Table 2 presents the corrected ITC and the Cronbach's alpha (if item deleted) values for the 17 item scale. The scale demonstrated good internal consistency reliability (Cronbach's alpha 0.873). Underlying factor structure of the scale was evident from Kaiser Meyer Olkin measure of 0.789. EFA using direct oblimin rotation with Kaiser normalization resulted in a four-component solution (eigenvalue >1). This four-component solution suggested by the "total variance explained" was confirmed by the scree plot [Figure 1]. The four components of CPBS-IHCW were identified as follows, after a series of consensus-building based on the content of items loaded on these components: "Personal vulnerability" (items 1, 3, 7, 8, 9); "workplace preparedness and safety" (items 10, 11, 12, 16, 17); "fear of societal prejudice and discrimination"

Figure 1: Scree plot

(items 5, 6, 13, 14); "family well-being" (items 2, 4, 15). The maximum possible score for CPBS-IHCW is 68, while the minimum score is 17. The component loadings, communalities, and the total variance explained by the factors in EFA are presented in Table 3. The four sub-scales of CPBS-IHCW accounted for slightly more than 73% of total variance. Item level DIF analysis,

Table 3: Pattern matrix from exploratory factor analysis showing the component loadings and communalities for the seventeen items of the CPBS-IHCW

Item	Factor 1	Factor 2	Factor 3	Factor 4	Communality
Item 1: How afraid are you of acquiring COVID-19 at work?	0.52				0.481
Item 2: How afraid are you that your family members may acquire COVID-19 because of you?				0.978	0.968
Item 3: How frequently are you feeling that you have acquired COVID-19?	0.615				0.55
Item 4: How concerned you are about the possibility of you propagating COVID-19 to your colleagues at workplace?				0.975	0.98
Item 5: How afraid are you that you and your family may experience discrimination from society as you are involved in COVID-19 duties?			0.72		0.686
Item 6: How anxious are you about the perceptions of the community during the isolation/self-quarantine period you will have to undergo after getting relieved from COVID-19 duties?			0.704		0.56
Item 7: How concerned are you that your involvement in COVID-19 related work may negatively affect your future professional duties?	0.95				0.845
Item 8: How frequently is your sleep getting affected because of thoughts relating to COVID-19?	0.94				0.86
Item 9: How afraid are you of dying from COVID-19?	0.504				0.54

KMO measure of sampling adequacy (0.789), Bartlett's test of sphericity - χ^2 (df)=3104.33 (136), $P < 0.001$, Extraction method=Principal components, Rotation=Direct oblimin rotation with Kaiser normalization, Factor 1=Perceived vulnerability, Factor 2=Work place preparedness and safety, Factor 3=Fear of societal prejudice and discrimination, Factor 4=Family well-being. df=Degree of freedom

done with ordinal regression, showed item bias for Item 11 with COVID-19 health care facility as the grouping variable [Table 4]. However, the magnitude of DIF was small (0.052). There were significant differences in CPBS-IHCW scores between participants serving at different COVID-19 health care facilities, with those participants from DCH demonstrating higher psychological burden scores compared to those serving in other types of facilities. This difference was also noted based on educational background, as the CPBS-IHCW scores of nurses were significantly higher than the participants from modern medicine and dentistry [Table 5]. An ICC (Two-way mixed effects model, single rater, absolute agreement) of 0.93 between test and re-test among 25 health care workers confirmed temporal stability of the instrument.

DISCUSSION

It is undeniable that the world would not be able to finish this COVID-19 marathon without the services of health care workers on the front line. In this process, the health care workers are exposed to numerous uncertainties, fears, and stressors. The aftermath of any epidemic would include psychological distress and social stigma.^[7,8] The world has experienced these psychological consequences previously during the time of influenza,^[23] SARS outbreak,^[24,25] and with the gradually evolved AIDS epidemic.^[26] Shanafelt *et al.* summarized the possible sources of fear and anxiety among health care workers during the COVID-19 pandemic; they have also discussed the conventional self-reliant nature of health fraternity as an important contributor to anxiety while dealing with a previously un-encountered

disease which is outside the professionals' area of clinical expertise.^[8] A validated scale to assess the psychological burden among health care professionals offering COVID-19 services goes a long way in supporting these professionals from the mental health and psychological end. In light of lack of psychometric tools to assess COVID-19 imposed psychological burden among health care workers, CPBS-IHCW offers a rapidly administrable and valid solution. To the best of our knowledge, this is the first COVID-19 psychometric instrument developed to assess the psychological burden among Indian health care professionals.

CPBS-IHCW showed good internal consistency reliability with Cronbach's alpha of 0.87, well above the cut-off suggested in literature.^[27] It is a rapidly administrable 17-item tool, using a semantic differential scale, which was considered over Likert scale to eliminate the potential acquiescence bias.^[28] The evaluative dimension is explicitly stated on a semantic differential scale rather than asking the subject to respond in affirmative or negative to a directive statement. EFA produced a four-factor solution reflecting the multidimensional structure of CPBS-IHCW. The correlation matrix between CPBS-IHCW and its four subscales confirmed that all the subscales are specific with regard to the measurement of the underlying construct of psychological burden; with moderate inter-sub scale correlation coefficients. The negative component loadings for items in "work place preparedness and safety" component were because the items were phrased in a reverse manner, that strong disagreement to these items increases the CPBS-IHCW scores, while it is the opposite for items loaded on the other three components. DIF analysis confirmed that there is no item bias in CPBS-IHCW, with no differences in item responses based on the type of COVID-19 health care facility and educational background, except for Item 11, the magnitude of DIF for which, however, is very small. As DIF assumes unidimensionality, DIF analysis was done separately for items loaded on the individual factors.^[29] It was identified that the health care workers serving in DCH had higher CPBS-IHCW scores which could be due to the more comprehensive and demanding nature of medical care provision for severe COVID-19 cases. This finding could be understood as provisional evidence for the construct validity of CPBS-IHCW. Nurses demonstrated higher CPBS-IHCW scores compared to health professionals from modern medicine and dentistry, the rationale for which, in the Indian context, could be the discrepancy between the level of information nurses have with regard to COVID-19 and the nature of duties they assume which demand closely working with infected persons. A study by Tan *et al.* among health care workers in Singapore in relation to the psychological impact posed by COVID-19 reported

anxiety among 14.5% and depression among 8.9% of the study sample.^[30] In the present study, no attempt was made to categorize participants based on CPBS-IHCW. Though there is limited consensus available on the recommended sample size for EFA, larger samples are conventionally advised. The sample size considered in this study is in accordance with the recommended subjects to item ratio of 30:1 in EFA.^[31] Smaller subject to item ratios of 6:1 were recommended and used in psychometric research.^[32,33] It is also noteworthy that psychological aspects are hugely culture-specific and no single instrument can be universally valid. Culture-specific, contextual instruments tested for psychometric properties are the need of the hour owing to immense variations in the work environments, cultural differences, health-related attitudes, and beliefs between health care workers from different countries across the globe. The results of this study need to be assimilated in light of the convenience sampling technique adopted in this study and the unequal gender distribution in the study sample.

CONCLUSION

Based on the results of this study, we conclude that CPBS-IHCW is a valid and reliable measure to evaluate psychological burden among health care workers operating at various levels, which is of great value in the assessment of psychological burden among health care professionals catering to the needs of the COVID-19 affected.

Acknowledgments

The authors sincerely acknowledge the contributions made by all the participating health care workers in this study to comprehensively understand the scenario and develop this instrument.

COVID-19 Psychological Burden Scale for Indian Health Care Workers (CPBS-IHCW)

1. How afraid are you of acquiring COVID-19 at work?
Extremely afraid ○ ○ ○ ○ Not at all afraid
2. How afraid are you that your family members may acquire COVID-19 because of you?
Extremely afraid ○ ○ ○ ○ Not at all afraid
3. How frequently are you feeling that you have acquired COVID-19?
Almost always ○ ○ ○ ○ Never
4. How concerned you are about the possibility of you propagating COVID-19 to your colleagues at workplace?
Extremely concerned ○ ○ ○ ○ Not at all concerned
5. How afraid are you that you and your family may experience discrimination from society as you are involved in COVID-19 duties?
Extremely afraid ○ ○ ○ ○ Not at all afraid
6. How anxious are you about the perceptions of the community during the isolation/self-quarantine period you will have to undergo after getting relieved from COVID-19 duties?
Extremely anxious ○ ○ ○ ○ Not at all anxious
7. How concerned are you that your involvement in COVID-19 related work may negatively affect your future professional duties?
Extremely concerned ○ ○ ○ ○ Not at all concerned
8. How frequently is your sleep getting affected because of thoughts relating to COVID-19?
Almost always ○ ○ ○ ○ Never
9. How afraid are you of dying from COVID-19?
Extremely afraid ○ ○ ○ ○ Not at all afraid
10. How satisfied are you with the training received in preparation for COVID-19 duties?

Tobacco Related Oral Lesions in South Indian Industrial Workers

Abstract

Introduction: Tobacco is the leading causative factor for both oral potentially malignant disorders and oral cancer. Tobacco use is higher among lower income population. Low-income population of India are majorly employed as industrial workers. The aim of this study is to estimate the prevalence of oral lesions associated with tobacco related habits among industrial workers. **Materials and Methods:** Cross-sectional epidemiological investigation was conducted among 1000 industrial workers using simple random sampling technique. Information on patient demographics, tobacco related (smoke and smokeless) and other deleterious habits, and clinical examination details were recorded in a structured format. The data were analyzed using Statistical Package for Social Sciences version 20.0. Results were tabulated using frequency distribution and mean with a standard deviation. Multiple logistical regression was used to analyze oral lesions by different variables. **Results:** Among the 1000 industrial workers screened, smoking habit was observed in 13.20%, while 86.8% were using smokeless tobacco. The prevalence of tobacco related oral lesions among individuals with smoke/smokeless tobacco habit was 13.8%. The study documented tobacco related oral lesions such as leukoplakia (6.5%), oral submucous fibrosis (2%), smoker's palate (2.7%), tobacco related pigmentation (1.9%), erythroplakia (0.3%), and oral squamous cell carcinoma (0.2%). **Conclusion:** The study documented potentially malignant disorders and oral cancer among users with tobacco related habits. The results also revealed that higher prevalence of potentially malignant disorders over oral cancer. Thus, preventive programs for early detection of oral precancer and oral cancer such as tobacco cessation, tobacco counselling programs are emphasized for industrial workers.

Keywords: *Epidemiology, occupation, oral lesions, tobacco, smoke, smokeless*

Introduction

Tobacco is considered a common risk factor for major noncommunicable diseases (NCDs). WHO stated that tobacco use is a major risk factor for NCDs, such as cardiovascular disease, cancer, chronic respiratory disease, and diabetes. Majority of tobacco consumers (particularly smokers) begin their habits during their early teen age. WHO predicted that tobacco users among younger individuals may lead to deaths of 250 million children and young people alive today. Majority of such populations are identified from the developing countries.^[1] WHO estimated in 2004 that 194 million males and 45 million females from India are consuming tobacco products to chew or smoke.^[2] In addition, WHO mentioned that India will observe the fastest death rate due to tobacco related conditions; however, this notation to death

reflects to NCDs and not necessarily to cancer related death. India has the highest number of oral cancer cases in the world due to the use of smokeless tobacco. Smokeless tobacco increases the risk of oral cancer development by sixfold.^[3] Oral cancer contributes to 30% of all cancer cases in India. Evidence-based reports mentioned that India has the highest prevalence of tobacco chewing (40%) and smoking (20%) population. Beedi smoking is a common type of smoking practice in India. Higher prevalence of smokeless tobacco users may be due to low cost, and often it is harder to recognize the habit of an individual by a member of their family, thus the habit of smokeless tobacco consumption remains unknown to family members.^[4]

Another justification for higher tobacco consumption in India may be attributed to Indian tradition which permits an individual to consume tobacco and areca nuts in different forms.^[5] A National Sample Survey from India stated that the prevalence of alcohol use is 4.5%, smoking tobacco is 16.2%, and chewing tobacco (smokeless tobacco) is 14%. The report also stated that tobacco related practices are common among males than females and rural than urban population.^[6]

Tobacco consumption is a harmful habit with the increased risk of oral potentially malignant disorders (OPMDs) and oral cancer. The changes in the oral mucosa may just begin as change in surface color or texture. Thus, lesions receive lesser attention by the tobacco consumer due to innocent appearing clinical presentation and are often neglected for early detection and care. Tobacco smoking is also a risk factor for periodontal disease and due to lack of awareness of routine dental examination among Indians, the cases with periodontal diseases are undiagnosed at an early stage. Various types of tobacco related products popular across Indian states are listed in Table 1. Although anti-smoking campaigns and mass media communication on patient education in newspapers, television, and radios are available, awareness on tobacco related practices remains an ongoing challenge in making an effective change. The challenges may be due to economic status, illiteracy, religious practices, psycho-social, peer and celebrity member influence, emotional, and family burden.^[5,7] Peer and celebrity member influence begins as a fashion smoking practice that may eventually turn into serious habit.

OPMD is a recent term used for referring to precancer, precursor, or premalignant lesion of oral cavity.^[8] The term OPMDs was coined with the notation that all lesions and conditions listed under this category are associated with increased potential for malignant transformation.^[9]

Table 1: Various types of tobacco related products identified across India^[7]

Region in India	Tobacco related products
Madhya Pradesh	Gutka
Gujrat	Gutka, Mawa, Bajjar
Arunachal Pradesh	Gutka, Gul
Bihar and Jharkhand	Khaini
Eastern India	Pan masala
Goa	Mishri, creamy stuff
Uttar Pradesh and Uttarakhand	Gul, Gudakhu
Manipur	Pan with tobacco, Hidakphu
Maharashtra	Mishri
Mizoram	Tuibur
Almost all regions of India	Smokeless tobacco or chewing tobacco, lal dant manjan

Existing literature on the frequency of tobacco related habits and oral lesions associated with tobacco related habits majorly focuses on youth/students, medical/dental students, loom workers, and tobacco workers. As mentioned earlier, two top reasons for the communication gap in attaining effective change from the anti-smoking campaigns are economic status and illiteracy.^[10] The authors of this study believe that the target population on low economic status and illiteracy may be identified in industrial workers. In addition, the number of industrial sectors in India is continuously rising in the recent decade.^[11] Hence, the data on tobacco related habits and oral lesions associated with tobacco habits will be useful for policy making decisions. Considering the importance of morbidity, quality of life, and influence on mortality, the study preferred to investigate the oral lesions related to tobacco habits linked to higher morbidity, negative impact on quality of life, and mortality [Table 2].^[12] Thus, the present study attempted to identify the prevalence of tobacco related habits and oral lesions associated with tobacco related habits among industrial workers in Andhra Pradesh, South India.

Materials and Methods

The current study is a cross-sectional epidemiological investigation conducted in industrial workers in Andhra Pradesh, South India from March 2018 to August 2018. The study was approved (protocol no. 128/IEC/ SIBAR/ 2018) by Institutional Ethics committee SIBAR Institute of Dental Sciences, Guntur on 6th Jan. 2018. Based on the industrial workers population in the study region, the sample size was estimated as 900 individuals with a 95% accuracy rate, a 95% confidence interval, and marginal error of 2%. Ten percentage oversampling with an additional approximation of 10 individuals was planned; hence, a total of 1000 individuals were recruited for the study.

Table 2: Tobacco related oral lesions categorized based on the level of morbidity impacting quality of life and mortality

Highly like to be associated with higher morbidity, negatively impact quality of life, and mortality	Highly likely to be associated with lesser morbidity, impact quality of life, and mortality
Oral squamous cell carcinoma/oral cancer	Discoloration of teeth, restorations, or denture
Oral leukoplakia	Periodontal disease
Erythroplakia	Reduced ability to taste or smell
Oral submucous fibrosis	Coated or hairy tongue
Smoker’s palate	Oral candidiasis
	Dental caries
	Increased failure rates for dental implants
	Smoker’s melanosis/pigmentation

The main aim of the study was to focus on tobacco related OPMDs; however, nontobacco related OPMDs may be encountered during data collection. Hence, for the convenience of the study, OPMDs were classified into the following sections:

- (1) Tobacco related OPMDs – Oral leukoplakia, erythroplakia, palatal changes with reverse smoking, oral submucous fibrosis
- (2) Nontobacco related OPMDs – Oral lichen planus, oral lichenoid lesions, graft versus host disease, discoid lupus erythematosus, epidermolysis bullosa, dyskeratosis congenita, actinic Cheilitis.

Study criteria

Sectional criteria of the study:

Inclusion criteria

- Individuals of 28 years and above
- Have signed informed consent form
- Individuals available on the day of screening

Exclusion criteria

Individuals who had acute and painful dental problems

Questionnaire focused on demographic details, tobacco related habit, and alcohol history was collected. The clinical examination was performed by a calibrated examiner with oral disease background. The lymph nodes were examined for all the participating individuals during extraoral examination. Basic dental examination instruments were used to conduct oral cavity examination. The individuals with clinically evident oral mucosal changes were subjected for toluidine blue and acetic acid staining for detection of OPMDs. The clinical information was computerized using Microsoft Excel documents and later subjected for statistical analysis using Statistical Package for Social Sciences version 20.0, Armonk, NY, IBM Corp.

Statistical analysis

The continuous variables in the data were mentioned as number, standard deviation, mean values, and proportions as percentages. The chi-square test was employed to assess the difference between the groups. Student *t* test was used to identify the mean exposure of tobacco habits. Multiple logistic regressions were used to analyze the oral lesions by different variables.

Results

The present study was conducted using a cross-sectional design with a WHO proforma for recording oral mucosal lesions and tobacco related habits among industrial workers in Guntur city. A total of 1000 workers from various industries who satisfied the exclusion and inclusion criteria of the study were individuals of 28 years and above and

individuals available on the day of screening. The study consisted of 53.9% of males and 46.1% of females. Majority of study participants were identified from 28 to 38 years of age intervals. The minimum number of participants was in the age group from 59 to 68 years. The mean age of the study population was 34.95 ± 11.97 years. In this study, 86.8% of individuals were chewing various forms of tobacco, whereas 13.2% were tobacco smokers. Gender distribution of tobacco smokers and smokeless tobacco users is given in Table 3. Age distribution of study participants of various forms of tobacco use showed statistical significance with $P \leq 0.001$. Age distribution of study participants based on various forms of smokeless tobacco practice showed higher levels of consumption of *khaini* than other forms of smokeless tobacco habits. Comparison of age distribution of study participants based on smokeless tobacco users and tobacco smoker showed both habits were prevalent from 28 to 38 years age group. Age- and gender-based distribution of study participants with and without tobacco related oral lesions is presented in Table 4. Both smokeless tobacco and tobacco users are highly prevalent in the age group from 28 to 38 years. Distribution of tobacco related oral lesions in various anatomic locations of oral cavity on both genders showed prevalence in the following order: buccal mucosa, labial mucosa, vestibule, corner of mouth, and palate. Buccal mucosa is the most frequently involved site for tobacco related oral mucosal lesions in both males and females. Distribution of tobacco related oral lesions (OPMDs) based on the age is presented in Figure 1(a).

Table 3: The frequency of smoke and smokeless tobacco users by gender

Gender	Smokeless tobacco	Smoking tobacco	<i>P</i> value
Male	408 (75.70%)	131 (24.30%)	0.00001*
Female	460 (99.78%)	1 (0.22%)	
Total	868 (86.80%)	132 (13.21%)	

* $P < 0.05$ is statistically significant.

Table 4: Age and gender distribution of tobacco related oral lesions among study participants

Age (years)	With tobacco related oral lesions	Without tobacco related oral lesions	Gender	With tobacco related oral lesions	Without tobacco related oral lesions
28–38	102 (10.2%)	712 (71.2%)	Males	138 (13.8%)	401 (40.1%)
39–48	14 (1.4%)	103 (10.3%)	Females	12 (1.2%)	449 (44.9%)
49–58	7 (0.7%)	87 (8.7%)	Total	150 (15.0%)	850 (85.0%)
59–69	4 (0.4%)	21(2.1%)			

Figure 1: (a) Distribution of tobacco related oral lesions in relation to age

Oral leukoplakia, erythroplakia, and oral submucous fibrosis are more frequently seen in the age group from 28 to 38 years. Gender distribution of tobacco related oral lesions showed predilection for males [Figure 1b].

Discussion

The study observed 53.90% males and 46.10% females. Our interpretation was similar to findings of Gupta and Ray,^[12] who found the maximum number of cases to be males (61.20%) than females (39.80%). The mean age of the present study was 27.95 ± 11.97 years, which ranges from 15 to 69 years. Most of the study population were from 20 to 29 years. Similarly, an Indian study reported in 2008 observed higher predilection in the age group from 20 to 30 years.^[13]

The current study documented 868 (86.80%) individuals with smokeless tobacco habits and tobacco smoking habit in 132 (13.21%) individuals. The study observed a similar prevalence rate of tobacco habit with a report from Goa, India.^[14] The current study reported tobacco smoking as 13.21%, and Goa study stated 15%. Another study from Andhra Pradesh reported smoking prevalence as 67%.^[15] The variation in the prevalence within the same geographic area should be attributed to industrial workers who probably may prefer the type of tobacco habit based on affordability. The cost range for smokeless tobacco may be way cheaper than smoking form of tobacco.^[15] Interestingly, consumption of smokeless tobacco was predominantly observed in females (99.78%) than males (75.70%).^[16] Similar findings were reported by Sankaranarayan *et al.*^[17] in 1989. Higher prevalence of smokeless tobacco among females may be related to social barriers for smoking form of tobacco among the women. Our qualitative interpretation on this item is that smokeless tobacco allows an individual to be pouched or snuffed in the oral vestibule and may go unnoticed by fellow work partners or family members. A study stated that the prevalence of OPMDs was higher among individuals with higher lifetime consumption of smokeless tobacco such as Pan Parag, Gutka, and Mawa.^[17] Our study reported that cigarettes are the most common form of smoking tobacco product, followed by cigarettes without

filter. Similar observation was made in the study conducted by Chandra and Govindraj^[18] in 2012.

The study observed oral leukoplakia, oral submucous fibrosis, and oral cancer to be more prevalent among the age group from 20 to 29 years (36.22%), which can be attributed as early consequences of tobacco related habits. Similar observation was observed in the study conducted by Mehrotra *et al.*^[19] in 2010. This study reinforces the concepts on association of tobacco products with OPMDs through the available data. A literature mentioned that any form of tobacco products may be associated with the occurrence of potentially malignant lesions.^[20] Leukoplakia is more commonly seen among males followed by oral submucous fibrosis. A less number of oral mucosal lesions were observed in females. This could be due to the fact that tobacco smoking is more commonly associated with oral mucosal lesions than smokeless tobacco. Smokeless tobacco is usually associated with oral submucous fibrosis and no other forms of oral mucosal lesions. In addition, traditionally males are more known to be affected by workplace related stress, financial burden, and psychological trauma due to lack of life partner or family issues. This study also supports the view that smokeless tobacco (Pan Parag, Mawa, and pan masala) is the risk factor for causing potentially malignant disorders and cancer.^[21,22]

Recommendations on social accountability from the findings of the study

Based on the interpretation of results, the authors of the study recommend the following for the policy making individuals: (1) Educational videos on self-screening for oral precancer and cancer, (2) workplace restriction on tobacco related products, (3) facilitation of outreach services of oral diseases by the management of industries, (4) collaboration of dental schools with industries for periodic oral cancer screening, (5) tobacco cessation and counselling programs among industry workers, (6) educating family members on the impact of tobacco related habits and oral health, overall health, and quality of life, (7) knowledge on the hospital costs involved in the late or terminal stages of oral cancer, (8) oral precancer or cancer month programs in industries, and (9) targeting the schools where children of industrial workers usually obtain their education for early education on tobacco related health and social hazards.

Conclusion

Leukoplakia, oral submucous fibrosis, and oral cancer are early consequences of tobacco related habits, whereas pigmentation and smoker's melanosis are late consequences. The study documented higher prevalence of oral lesions related to tobacco habits among industrial workers. The study emphasizes the importance of special preventive programs targeting industrial workers including self-screening for oral precancer and cancer, tobacco cessation, counselling programs,

and early detection of oral cancer. Workplace restriction for smoking or smokeless tobacco, educating family members on tobacco related oral lesions and its impact on health, and overall health and lifestyle may also play a role in bringing forward a societal change.

Abstract

Purpose: Intraoral defects in the maxilla cause communication with the nasopharyngeal complex. The surgically removed palate can have a devastating effect on the appearance and speech of the patient. Obturators allow patients to eat and drink without any suspicion of food entering the oroantral cavities/ pharynx during mastication. This clinical report describes fabrication of a closed hollow bulb obturator using the two-piece double flask technique.

Method: After the final teeth arrangement was completed, teeth over the defect were removed and separately processed using heat cure acrylic resin. Both the segments are combined by autopolymerizing acrylic resin to form a single hollow-bodied obturator.

Conclusion: This technique uses a double flasking method of the two segments to control the thickness of the bulb in the defect area, thus decreasing the weight of the obturator.

Keywords: Maxillary defects, Obturators, Hollow bulb, Post-Covid Mucormycosis

1. Introduction

Resection of maxilla due to tumors or any infection leads to facial disfigurement, impaired functions like speech due to hypernasality, rumination, and a significant impact on patients quality of life. Post COVID-19 sepsis is that which occurs after SARS- CoV-2 had a rampage in the human body. It leads to ciliary dysfunction, cytokine storm, thrombo-inflammation, microvascular coagulation, and eventual immune exhaustion. This cascade of events facilitates secondary bacterial and fungal infections, especially in critically ill patients subjected to invasive emergency procedures, mechanical ventilation, prolonged hospital stays, and breaches in asepsis. Further, corticosteroid treatment in these highly susceptible hosts and high fungal spore counts in the environment creates the perfect setting for mold infections. ⁽¹⁾

The infection begins in the nose and paranasal sinuses due to the inhalation of fungal spores. ^(2, 3) This infection can spread to the orbital and intracranial structures by direct invasion or through the blood vessels. ^(4, 5) The fungus invades the arteries leading to thrombosis that subsequently causes necrosis of hard and soft tissues. Early diagnosis and treatment can reduce the mortality and morbidity of this lethal fungal infection. Treatment principles may include antifungal agents along with surgical debridement or resection.

This article discusses an innovative fabrication technique of obturator to treat an acquired maxillary defect due to post Covid-19 mucormycosis. Management of such maxillary defects when surgical resection was performed requires a multidisciplinary approach. Prosthodontic rehabilitation is the most practical, convenient, and cost-effective treatment mode and the added advantage of removing prosthesis and evaluating the infected site efficiently.

2. Case Report

A 65-year-old male patient reported to the Department of Prosthodontics with a chief complaint of difficulty in consumption of food and speech discrepancies. Intraoral examination revealed ~~large maxillary defect~~ on the left side with oroantral communication and partially edentulous arch. (Fig 1)

Fig. 1) Pre-operative intra oral view

On past medical history, it was found that the patient underwent maxillectomy for post Covid-19 necrosis of maxilla due to mucormycosis six months back. The treatment plan was to fabricate a hollow bulb obturator using a two-piece double flask technique.

3. Treatment

A linear design for a Class-IV defect was selected for this case according to design principles described by Aramany in 1978 in which remaining palatal tissues provided the support and retention was achieved from the ball end clasps and C clasps made on the remaining intact dentition. ⁽⁶⁾

Fabrication of the Obturator

A primary impression was made with irreversible hydrocolloid impression material (Fig 2 a) using a stock tray. After obtaining the primary cast, (Fig 2 b) a special tray was fabricated with self-cure acrylic resin.

Fig. 2 a) Primary impression with irreversible hydrocolloid

Fig. 2 b) Primary cast

Border moulding was done (Fig 3a) with greenstick material and the full extent of the defect was recorded using an impression compound. 1mm impression compound was scraped, and a light body secondary impression was made to record the undercuts which aid in anatomic retention. A final pick-up impression was made with alginate to record existing dentate segment (Fig 3 b). The master cast was obtained with type IV gypsum (Fig 3 c).

Fig. 3 a) Border moulded impression & the extended depth of defect recorded

Fig. 3 b) Secondary pick up

Fig. 3 c) Secondary cast of maxilla

A temporary denture base with occlusal rim was fabricated on the master cast. Bite registration was done. Maxillary and mandibular casts were mounted on the semi-adjustable articulator (Hanau wide vue). Teeth arrangement and try-in were done. Occlusion, aesthetics, and phonetics were evaluated and found to be acceptable by the patient. A C-clasp on canine and molar as well as ball-ended clasps in the embrasures between canine and premolars were given (Fig 4). The final wax-up was done.

Fig 4) Final wax up & clasps placed for retention

Procedure for Two-Piece Hollow Obturator

The teeth overlying the defect area were cut (Fig 5), and the defect area was hollowed out. The hollow space was filled with putty material (Fig 6a), over which a segment with the posterior teeth was fabricated (Fig 6b).

Fig 5) Teeth portion over the defect area removed

Fig 6 a) Putty packed into the defect Fig. 6 b) Second segment fabricated

Orientation grooves were placed to prevent the misfit of the two pieces after fabrication and were re-checked for occlusion on the articulator. Both the segments were flaked and processed separately. (Fig 7, 8)

Fig.7) Flasking of the two segments separately

Fig 8) Mould spaces created

After retrieval, the segments were approximated with sticky wax before the obturator was removed from the cast (Fig 9a). Occlusion was checked by remounting the cast and the approximated segment onto the articulator (Fig 9b).

Fig 9 a) Approximated segments & stabilized using sticky wax

Fig. 9 b) Occlusion is checked after remounting

The necessary corrections were made, and finally, the two segments were adhered using auto polymerizing clear acrylic resin. After final finishing and polishing, the prosthesis was weighed 29 grams (Fig 10 a, b). Insertion of the prosthesis was done (Fig 11 a, b) and post-insertion instructions were given.

4. Discussion

The primary goal of a prosthodontist is to rehabilitate a maxillary defect by closing the oronasal communication with a retentive and a stable seal using an obturator. Extension of the bulb into the maxillary defect is advantageous to provide resonance during the speech. The fabrication of a hollow bulb obturator in patients with severe maxillary defects can provide retention and stability by decreasing the weight. There are many techniques for fabricating hollow bulb obturators by using sugar, salt, or alum in the defect area while packing. Matalon and LaFuente⁽⁷⁾ used sugar during the processing of the obturator, which was removed by drilling a hole. Iramaneerat *et al.*⁽⁸⁾ used the technique of injecting argon gas into the obturator bulb. Buzayan *et al.*⁽⁹⁾ used a rigid thermoforming splint to fabricate a hollow bulb obturator. Asher *et al.*⁽¹⁰⁾ used plaster index as a matrix to fabricate a hollow obturator.

El Mahdy *et al.*⁽¹¹⁾ described the two-flask technique to process the obturator and the tooth portion separately. Mc Andrew *et al.*⁽¹²⁾ fabricated the prosthesis in two halves and sealed them using autopolymerizing resin. Few authors suggested the use of acrylic resin shim and polyurethane foam while packing.⁽¹³⁾ Use of attachment for hollow bulb obturators, though advantageous, the cost of treatment would be high.⁽¹⁴⁾

5. Conclusion

Fabrication of a two-piece obturator using the double flasking technique is an easy and conventional method. Hollowing of the obturators not only reduce the weight but also adds resonance to speech. The defect was closed, and a satisfactory esthetics, phonation and function was achieved. Prosthetic rehabilitation will improve the patient's quality of life and confidence.

New Classification System for Cleft Alveolus: A Computed Tomography-based Appraisal

Philip Mathew¹, Vivekanand S Kattimani², Rahul VC Tiwari³, Mohammad S Iqbal⁴, Aisha Tabassum⁵, Khalid G Syed⁶

ABSTRACT

Aim: The present study proposed a new classification system based on computed tomography (CT) scan appraisal; this enables the surgeon to identify the extent of the defect and helps to execute the proper treatment plan.

Background: Various terminologies and classifications were proposed to understand developmental defects. But none of the existing classifications/nomenclatures used the preoperative radiographic evaluation (i.e., computed tomography scan—CT scan) in the management and prognosis. Various treatments were advocated and practiced successfully for the surgical correction of lip and palate.

Materials and methods: The available CT scans from archives of the Department of Radiology and Oral and Dental Surgery were evaluated (retrospectively) for cleft alveolus and its morphology as per the proposal. The English language literature was searched in the MEDLINE database without date restriction to revise existing literature on numerous classification systems/nomenclatures using MeSH keywords related to cleft lip, palate, alveolus, developmental disturbance, facial clefts, and classification. Existing classification systems were revisited with a note on the drawbacks. After careful examination of morphological patterns of all clefts, the new CT scan-based alveolar cleft classification is proposed depending on the extent of cleft.

Results: The literature revealed a total of twenty-nine classifications of cleft lip and palate starting from the year 1922 to the year 2015, but none exclusively classified the cleft alveolus based on CT scan observations. The observation of three thousand CT scans showed five types of cleft alveolus, depending on the extent of involvement.

Conclusion: The CT scan-based classification is essential to the surgeon for successful surgical planning of cleft alveolus. The proposed classification is clinically relevant in this digital era for relating surgical outcomes. The three-dimensional viewing of a defect is essential for the surgeon for virtual planning. This paper provides a CT scan-based classification for universal acceptance in this era of digital technology, and CT scan aids in achieving these goals.

Clinical significance: The new proposal is based on preoperative evaluation of cleft using a CT scan. CT scan imaging provides a clear picture of the cleft in three dimensions for the operating surgeon. Advanced technology-enhanced surgical management modalities like CAD/CAM guided templates to support graft for successful management. The classification system will help the medical and surgical fraternity in various aspects. The three-dimensional modeling of defect and printing of a defect model using additive manufacturing technology helps the surgeon for presurgical visualization and virtual planning in a better way. This strategy of defect classification using a CT scan will help obtain better clinical outcomes and patient satisfaction.

Keywords: Alveolus, Anomaly, Cleft, Embryology, Nomenclature, Repair.

The Journal of Contemporary Dental Practice (2020): 10.5005/jp-journals-10024-2849

INTRODUCTION

Various classification systems were proposed from the beginning of the era.¹ Many surgeons and clinicians came out with different classification systems. Time immemorial, the classification/nomenclature started with notations so that it can be stored and retrieved digitally.² The wide diversity of cleft lip and palate in terms of clinical presentation makes the universal acceptance of existing classifications difficult,³ and specific cleft alveolus classification does not exist.

The cleft alveolus is an entirely separate entity than a cleft of the palate. It should be viewed in the spectrum of cleft lip.⁴ The existing classifications are either combined with lip, palate, or both, because of the nature of cleft development (Table 1). The isolated occurrence of the cleft alveolus is rare, which might be one of the reasons for not having separate classification. The difference of opinion and need for a universally accepted classification made our team think of a computed tomography (CT) scan-based classification system and factors affecting the prognosis before surgical management. The existing literature proposed many treatment modalities, pre- and postoperative expansion of the maxilla, and schedules for

Table 1: Existing classification chronologically with comments

S. no.	Proposed by	Year	Comments
1	Davis and Ritchie ⁵	1922	Based on the alveolus, patients with a unilateral or bilateral cleft of the lip and posterior palate with intact cleft alveolus fail to fit into a single group.
2	Victor Veau ⁶	1931	Used incisive foramen as an anatomic landmark for the division of types, but overlooked the cleft patients born with cleft lip, alveolus.
3	Fogh-Andersen ⁷	1946	Based on anatomy and embryology, and the concept of primary and secondary palates involved for grouping.
4	Kernahan and Stark ⁸	1958	Used embryological concepts and primary and secondary palates for description purposes.
5	Vilar-Sancho ⁹	1962	Used Greek nomenclature for classification and coded congenital cleft lip and cleft palate. It could not classify many of the cleft subtypes, even though included alveolus as "G" (gnato) with the right, left, complete, and incomplete. But not adopted worldwide probably because it was in Greek.
6	Harkins et al. ¹⁰	1962	Based on anatomic segmentation into the pre-palate and the palate with subclasses. The subclasses used severity, i.e., quantitative measurement of width and extent of cleft as 1/3, 2/3, or 3/3, but no specific mention of alveolar subclass was made in the classification.
7	Santiago ¹¹	1969	Based on digital and alphabetical notification involved all types for the use of machine coding but not specifically concerning the extent of alveolus as they mentioned either complete or incomplete, unilateral or bilateral.
8	Dahl ¹²	1970	A combination of clefts classification is not possible.
9	Fogh-Andersen ¹³	1971	Modified the original types by adding a new group to feature the median clefts.
10	Kernahan ¹⁴	1971	Described using a Y-shaped diagram representing lip, palate, and alveolus. This notification is merely visual and failed in the application aspect.
11	Elsahy ¹⁵	1973	This is a modified striped Y classification.
12	Spina ¹⁶	1973	Described a modification of terminology in international classification by adding Latin term "foraminal."
13	Balakrishnan ¹⁷	1975	Based on anatomical and embryological representation and was based on Dahl 1970 classification.
14	Sandham ¹⁸	1985	This is modified from Kernahan and Stark.
15	Kriens ¹⁹	1989	Proposed LAHSHAL classification, with acronym lip, alveolus, hard palate, soft palate. The last three words will be for the left side, and the first three words will be for the right side. Because of its verbal communication in different languages its use is limited.
16	Silva Filho et al. ²⁰	1992	Modified Spina classification with the inclusion of group I/III for stratification, but it did not assess cleft severity (cleft size) and the capacity for prognosis estimation.
17	Schwartz et al. ²¹	1993	Proposed an RPL system with numerical coding for easy presentation.
18	Koch et al. ²²	1995	Proposed LAHSN (lip, alveolus, hard and soft palates, and nose) based on the extent in all three directions.
19	Smith et al. ²³	1998	Modified classification of Kernahan striped to compensate for the shortcomings and added additional types. But it did not describe the submucous cleft palate levels nor the alveolus.
20	Ortiz-Posadas et al. ²⁴	2001	Developed mathematical expression for characterization to reflect overall complexity.
21	Castilla and Orioli ²⁵	2004	Presented ECLAMC numerical coding system. This classification presented numerical code for all possible varieties and extent, but did not mention the prognostic factors. It is similar to our presentation, but little variation exists in the use of terminology.
22	Liu et al. ²⁶	2007	Developed (LAPAL system) a five-digit numerical recording system based on Kernahan "Y" classification, Smith-modified Kernahan "Y" classification, and the RPL system. The extent of defects was represented by Arabic numerals (0-4).
23	Koul ³	2007	Used anatomical nomenclature (text) and symbols for proposal. It looks complicated because of the symbols involved in the presentation.
24	Yuzuriha and Muliken ²⁷	2008	Described less form labial clefts with measurements of 3 mm more or less as micro, mini-micro. This presentation includes the operative guide for optimal operative technique depending on the severity of the cleft.
25	Rossell-Perry ²⁸	2009	Proposed classification of severity and diagram for cleft description. Also discussed the selection of proper technique depending on the class of cleft. The severity of the cleft was assessed by the width of cleft and sum of width of the two palatal segments at the junction of soft and hard palates to indicate the tissue deficiency. Based on measurements, the index classifies three degrees of severity for the cleft palate but does not consider alveolus for the same.
26	Khan et al. ²⁹	2013	Revised Smith-modified Kernahan "Y" classification with submucous cleft varieties, but these subclassifications did not consider alveolus.

S. no	Proposed by	Year	Comments
27	Agarwal ³⁰	2014	Modified Indian classification described by Balakrishnan into groups with a notation of '+' for unilateral and bilateral combinations and abbreviations of the involved part.
28	Luijsterburg et al. ³¹	2014	Based on patho-embryological events like fusion, differentiation, and fusion and differentiation defects of the primary and secondary palates.
29	Allori et al. ¹	2015	Proposed a universal structured form in the form of CLAP notation.

Table 2: Proposed classification for alveolar cleft based on preoperative 3D computed tomography

Class	Description	Nature	Comments	Prognosis
I	One-third alveolus involvement	Submucosal, isolated, unilateral, or bilateral	Tooth involved may be erupted/partially erupted/impacted	Good
II	Two-thirds alveolus involvement	Submucosal, isolated, unilateral, or bilateral	Tooth involved may be erupted/partially erupted/impacted	Good, requires prosthetic or orthodontic treatment
III	Complete alveolus involvement	Isolated, unilateral, or bilateral	Tooth involved may be erupted/partially erupted/impacted	Good, requires prosthetic or orthodontic treatment
IV	Communication with nasal floor	unilateral, or bilateral complete	Tooth involved may be partially erupted/impacted	Depends on the width of cleft and requires prosthetic or orthodontic treatment
V-A	Concomitant with lip and palate	Associated with Class I	Any lip or palate cleft as described previously, might be associated with Class I alveolar cleft	Good with alveolus, but the overall result depends on the associated nature of clefts
V-B	Concomitant with lip and palate	Associated with Class II	Any lip or palate cleft as described previously, might be associated with Class II alveolar cleft	Good with alveolus, but the overall result depends on the associated nature of clefts
V-C	Concomitant with lip and palate	Associated with Class III	Any lip or palate cleft as described previously, might be associated with Class III alveolar cleft	Depends on the width of cleft and the associated nature of clefts and may require a second surgery

alveolar cleft grafting. Grafting of cleft alveolus uses autologous and synthetic bone substitute materials. With our knowledge, none of the published studies have given specific graft material nor advised a standard surgical technique in a particular defect class.

This study proposed a CT scan-based new classification appraisal for cleft alveolus exclusively, after morphological examination of cleft patterns using CT scans (archives of more than 3000 alveolar clefts—both unilateral and bilateral cases) in our center. This study delineates our center management strategy to understand the prognostic factors depending on the new CT-based cleft classification.

MATERIALS AND METHODS

The CT scans of the cleft patients with an age range of 9–20 years from the archives of the Department of Radiology and Oral and Dental Surgery were included for evaluation. The data were evaluated for cleft morphology, and other factors were noted retrospectively to understand the outcomes of surgery. Various cleft defects were appraised and noted as per the new classification. The grafting, defect correction, and its outcomes were noted for surgical emphasis as per our center's protocol based on CT scan.

The English language literature was searched in the MEDLINE database without date restriction to revise existing literature on numerous classification systems using MeSH keywords related to cleft lip, palate, alveolus, developmental disturbance, facial clefts, classification, and nomenclature. Cross-reference search was performed in various plastic and reconstructive journals, head, and neck, oral and maxillofacial journals for comprehensiveness.

RESULTS

The CT scan examination revealed five types of defects. These defects were grouped into five classes, annexed with subclasses (Table 2). The literature revealed a total of twenty-nine classifications/nomenclature of cleft lip and palate since the year 1922 till 2015 (Table 1). Still, none exclusively described cleft alveolus based on CT scan observations.

DISCUSSION

Historically, cleft classification or nomenclature descriptions were given by Davis and Ritchie⁵ way back in the year 1922, followed by many other studies^{1,3,6–31}, as noted in Table 1 with comments. But none of these existing classifications/nomenclatures mentioned cleft alveolus appraisal based on preoperative CT scan examination. The recent explanation of cleft alveolus has noted the historical discrimination of distinguishing it from the palate has not been made clear, which needs to be corrected for proper attention and treatment.⁴ The inadequacies of each classification are mentioned in Table 1 with comments. The advances in radiographic investigations from plain to three-dimensional imaging made the preoperative evaluation and virtual planning more easy and accurate. In the absence of a patient, the surgeon will be able to plan it accurately and discuss with peers before surgery for successful execution as planned using a CT scan.

Proposed Cleft Alveolus Classification

The new classification proposal is based on the preoperative CT scan views of defect patterns and morphology. In the proposed classification, cleft alveolus is divided into five major classes as Class I

to Class V with three subclasses in Class V (Table 2), either unilateral/bilateral depending on the extent of alveolar cleft measuring from the crestal bone of adjacent teeth. The schematic diagram and corresponding representational CT scan images delineate the proposed system of classification for better understanding (Figs 1A to 4A and Figs 1B to 4B). This system considers the depth and width of cleft and thereby helps the operating surgeon for proper planning of the treatment. In concomitant clefts of lip and palate (proposed Class V and its three subdivisions), the surgeon or clinician can adopt any one of the classifications depending on their geography and school of thought for the treatment. Many of our clefts fall in Class V with subclasses; this might require a second surgery for an esthetic correction after the growth of the patient ceases.

The timing for repair of cleft lip and palate were well-established facts in the published literature.³²⁻³⁵ The grafting for alveolus was also proposed and practiced widely.³⁶⁻³⁹ But none of the published literature classified cleft alveolus based on preoperative CT scan findings in three dimensions. The advances in diagnostic technology, both prenatal and postnatal, to assess developmental and growth disturbances for predicting anomalies are much better than earlier. Anomaly scanning of parents has

reduced the newer incidence of clefts reasonably. These reducing trends in the defects might be one of the reasons for not having enough number of cases to standardize the existing classification or providing a newer appraisal.⁴⁰ The historical presentations were based on clinical and intraoperative findings. Liu et al.,²⁶ Yuzuriha and Mulliken,²⁷ Rossell-Perry,²⁸ Khan et al.,²⁹ and Agarwal³⁰ classifications have similarities with the proposed classification, but none have a specific description of cleft alveolus using CT appraisal. The present appraisal is distinct and provides better prognostic features. The advances in technology help to create a virtual model for the reconstruction of these defects using CAD/CAM.

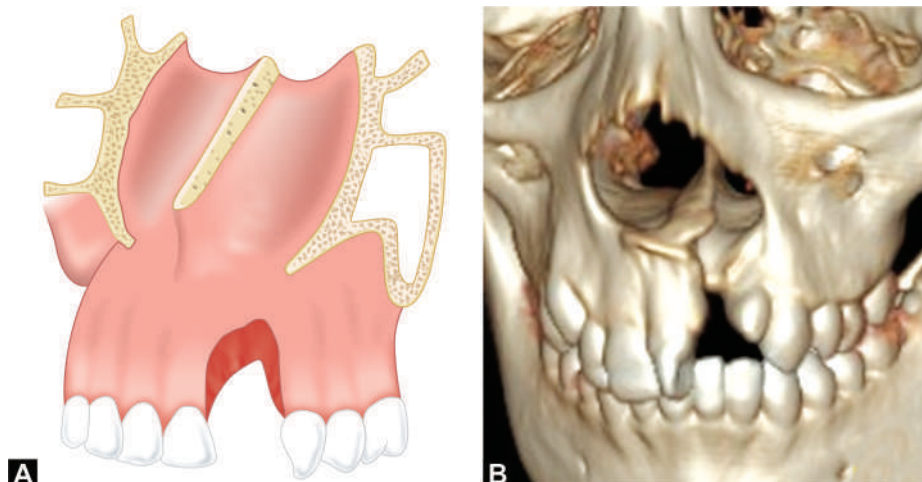

Our Center’s Protocol for the Management

Description of treatment options as per CT-based classification is as follows:

Classes I and II—use of cancellous alveolar bone grafting, platelet rich fibrin (PRF) membrane placed along the oral surface of the graft. Class III—use of corticocancellous alveolar bone grafting to provide mechanical strength to the graft. PRF membrane was placed along the oral surface of the graft. According to the subdivisions of the proposed classes, the involvement of the nasal floor and depression of the alar base on the affected side(s) should be considered. If the

Figs 3A and B: (A) Schematic diagram and (B) representative 3D CT scan image showing Class III alveolar defect

Figs 4A and B: (A) Schematic diagram and (B) representative 3D CT scan image showing Class IV alveolar defect

nasal floor is involved, an additional PRF membrane has to be placed along the nasal floor mucosa and a thin piece of cortical bone is used to separate the nasal mucosa up to the level of nasal floor, for example, to the same height of the opposite unaffected side in the unilateral cleft. This cortical bone piece acts as resistance while packing the defective area with cancellous bone. The pyriform rim on the affected side[s] in the region of the depressed alar base also needs to be grafted with corticocancellous bone.

Factors Affecting the Prognosis of Cleft Alveolus

The prognosis of cleft alveolus surgery is multifactorial. It can be broadly divided into operator and patient factors. Patient factors include nature and type of cleft. The width of the cleft is considered as one of the critical factors for the success of the graft. Various surgical grafting techniques and adjunct presurgical treatment modalities like naso-alveolar molding for aligning the cleft segments are practiced by clinicians.¹² Grafting strategies of the cleft are well published in the literature.⁴⁰

Limitations of the Study

The study data were collected retrospectively, so the correlations of various factors for the outcome analysis were not considered.

The study also not considered scans of older age-group patients (above 20 years). The surgical modalities are not compared for the esthetic outcome, nor the data available were considered in the surgical and follow-up notes. The prospective study is ongoing to delineate the various factors affecting the prognosis of cleft grafting, taking into consideration new CT scan-based classification. The photographic outcome and patient satisfaction index studies are also ongoing in our center. This is preliminary work on the archival data of CT scan-based morphological examination of the cleft alveolus.

CONCLUSION

The proposed classification is useful for research and clinical purposes. Meticulous planning is required for the successful execution of surgery. By knowing the posterior extent of the cleft in the hard palate using a CT scan, one should be cautious to avoid overpacking of the defect. The new proposal is unique and provides insights into cleft alveolus may be isolated or concomitant. The prognosis of surgery invariably depends on the nature of clefts. It can be used for future reference in systematic reviews. The standardization of defects will provide proper evidence for treatment modalities in this evidence-based digital era.

AUTHOR CONTRIBUTIONS

Philip Mathew and Vivekanand S Kattimani drafted the protocol and developed a search strategy; Team 1, Philip Mathew, Vivekanand S Kattimani, Rahul Vinay Chandra Tiwari, and Team 2, Mohammad Shahid Iqbal, Aisha Tabassum, Khalid Gufran Syed, searched for literature. Vivekanand S Kattimani and Philip Mathew selected articles to include in this analysis. Philip Mathew and Rahul Vinay Chandra Tiwari performed archival data extraction for analysis. Mohammad Shahid Iqbal, Aisha Tabassum, and Khalid Gufran Syed obtained copies of publications of all included studies. Vivekanand S Kattimani and Rahul Vinay Chandra Tiwari extracted data from publications. Mohammad Shahid Iqbal and Aisha Tabassum verified the data entered for review. Vivekanand S Kattimani, Rahul Vinay Chandra Tiwari, and Philip Mathew interpreted the CT scan data; Philip Mathew and Vivekanand S Kattimani drafted the final evaluation and interpretations. All the authors read and approved the final version of the manuscript.

ACKNOWLEDGMENTS

The authors thank the colleagues of the Radiology Department for their help in retrieving the CT scans for assessment and for extending support to provide the needed CT scan sections for appraisal. The authors also thank colleagues Dr Lakshmi Manas and Dr Anita for their inputs during manuscript revision and Ms. Nandini for helping with diagrammatic presentation.

Quality Assessment of Systematic Reviews of Temporomandibular Joint Ankylosis Surgical Treatment Outcomes

Vivekanand S Kattimani¹, Abhishek Jairaj², Nikhil O Govindan³, Paul Mathai⁴, Swati Sahu⁵, Abhishek Patley⁶, Parveen S Sultana⁷

ABSTRACT

Aim: Temporomandibular joint ankylosis (TMJA) management involves many surgical treatment modalities depending on the experience of the operator. A lot of literature has been published on various treatment modalities. Many systematic reviews (SRs) were published without any published prior protocol. So, the study aimed to evaluate the quality of SRs with meta-analysis of TMJA management.

Materials and methods: Systematic reviews with meta-analysis were included for the quality assessment using AMSTAR (assessment of multiple SRs) and Glenny et al. checklist by two independent teams. The search was limited to the Medline database archival (from January 1980 to December 2018).

Results: The primary search identified 1,507 related articles. After activation of different filters, abstracts screening, and cross-referencing, finally, a total of six studies were assessed to make the overview up-to-date.

Conclusion: The articles scored 8 to 11 with AMSTAR and 7 to 13 with the Glenny et al. checklist. None of the published reviews received maximum scores. The methodology and heterogeneity are essential factors to assess the quality of the published literature.

Clinical significance: None of the included meta-analysis was registered or published protocol with Prospero or Cochrane before publication for better validity of the studies. The authors are advised to follow reporting criteria so that in the future it is possible to provide the standards of care for TMJA with the highest quality of evidence.

Keywords: Condyle, Cranium, Diarthrodial joint, Evidenced-based dentistry, Systematic review.

The Journal of Contemporary Dental Practice (2020): 10.5005/jp-journals-10024-2766

INTRODUCTION

Clinical decision making for the treatment approach in dentistry or medicine depends on evidence, published in peer-reviewed journals.¹⁻³ The decision for the standard of care for any treatment and recommendation depends on remarks of systematic reviews (SRs), randomized-controlled trials (RCTs), cohort studies, and least with retrospective studies.⁴ For few entities like temporomandibular joint ankylosis (TMJA), it is difficult to find RCTs because of less number of patients with similar clinical presentation, availability of many surgical modalities, and varied clinical scenario of ankylosis. So, it is difficult to ascertain and recommend a single modality of treatment or standardization of methodology. Because of these prevailing factors, the clinician will be in a dilemma during the selection of treatment modality.⁵ In recent years different protocols were developed, modified for the management of ankylosis.^{6,7} Thousands of articles were published regarding the management of TMJA. But this evidence is questionable because of varying methodologies and difficulty in reproducibility as ankylosis management and prognosis are multifactorial. So, biomedical journals started following standard publishing guidelines to maintain uniformity while reporting.⁸

In recent past, publishers adopted various reporting guidelines like CONSORT (Consolidated Standards of Reporting Trials), STROBE (STrengthening the Reporting of OBservational studies in Epidemiology), SPIRIT (standard protocol items for clinical trials), SQQR (standards for reporting qualitative research), etc., for various types of article publications.⁸ These guidelines help clinicians to prevent publication bias. Multiple tools were also developed to

critically analyze the methodological quality of SRs and provide the recommendations based on the highest evidence.⁹⁻¹²

The available SRs showed that only 40.5% of the studies assessed the risk of bias/quality.³ Till date, quality assessment of the published reviews on TMJA had not been performed.^{2,13} In the wake of this diversity, the overview of SR articles with meta-analysis (MA) regarding comparative surgical treatment outcomes of TMJA was planned to assess and compare the quality using two types of tools: AMSTAR⁹ (assessment of multiple SRs) and the Glenny¹⁰ checklist.

MATERIALS AND METHODS

An electronic search was performed with the date and no language restriction. The search included articles published from January 1980 to December 2018 using various Boolean operators with multiple combinations of search strings in the Medline database. Depending on the title, abstract and full-text articles published in the English language were selected for reading with the following selection criteria to ascertain the objective. Only published articles of TMJA surgical treatment outcomes SR with MA were included for assessment. After initial screening, full-text articles were selected for critical reading and analysis. The authors were contacted for further clarification if the ambiguity in the published data exists. Two independent teams assessed the quality of included studies using AMSTAR⁹ and the Glenny et al.¹⁰ checklist.

The scoring was performed according to the characteristics of the study for a quality check as per the checklist. These criteria were based on the questions framed by AMSTAR⁹ and Glenny et al.¹⁰ for the assessment of quality check of published SR and MA. These questions assess how well the SR and MA were performed to reach the consensus on the treatment outcomes depending on the objectives of the study. The AMSTAR⁹ checklist consists of 11 questions, whereas the Glenny et al.¹⁰ list consists of 14 questions to assess quality. These questions/evaluative factors assess search criteria, methodology, the prior publication of the protocol, the validity of statistics of included studies, consideration of bias factors, any missing data, method of data collection, scientific quality, heterogeneity, and conclusive remarks based on the rationale supported by outcomes of the included primary studies. Differences in scoring among the two teams sorted with discussion. The methodological quality and statistics was assessed by a team of review members involving a public health dentist. The following search criteria with MeSH words were applied to generate the required data from the Medline archival.

Search Criteria and Data Screening

A literature search was performed using four search categories, which included various Boolean operators and MeSH keywords related to treatment outcomes of surgical management of TMJ ankylosis (Table S1 supplementary material).

Statistical Analysis

The data were collected using both quality assessment tools and were analyzed using descriptive statistics. The Spearman correlation test was performed for determining correlation between the two scoring criteria.

RESULTS

After going through the abstract of all final results of four search categories (Table S1) and narrowing down the search to address the objective of quality assessment, authors found 10 publications (Flowchart 1). After going through full-length articles, out of ten, one

Flowchart 1: Screening and selection process

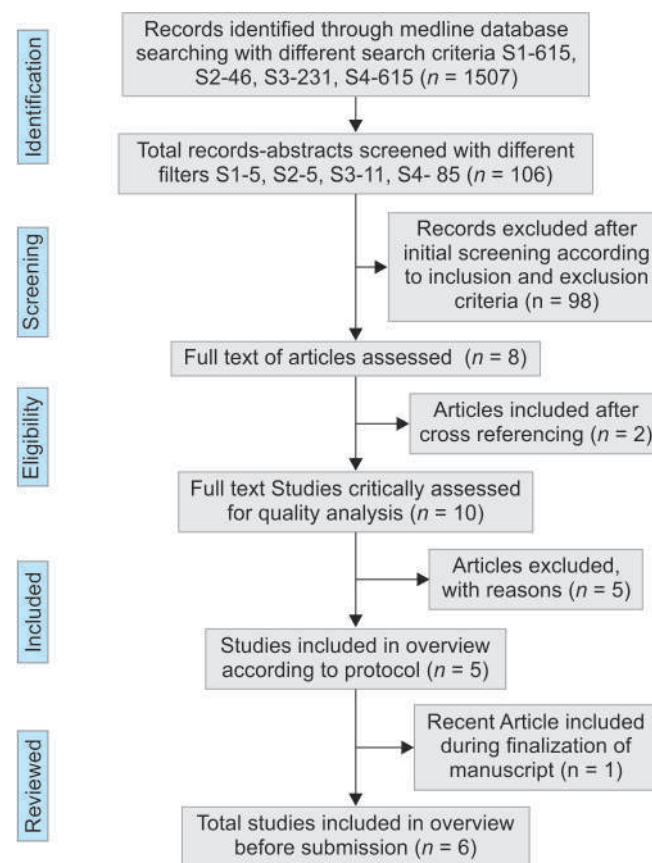

Table 1: List of excluded studies and the reason for their exclusion

Author and year	Reason for exclusion
Sporniak-Tutak et al. ¹⁴ (2011)	Descriptive review
Movahed and Mercuri ¹⁵ (2015)	Descriptive review
Sharma et al. ¹⁶ (2017)	Descriptive review
Bénateau et al. ¹⁷ (2016)	Other than the English language (in French)
AAOMS ParCare ¹⁸ (2012)	Not focused exclusively on comparative TMJ surgeries

was in the French language, another was American Association of Oral and Maxillofacial Surgeons (AAOMS) guidelines not focused on comparisons, and three were descriptive reviews focused mainly on the effects of various surgical treatment modalities in ankylosis without MA (Table 1).¹⁴⁻¹⁸ Five studies were found eligible for the review, but our team found one more recently published study,⁵ which has been added for final assessment to make an effort more complete and up-to-date and which rose the total number of included studies to six.

Study Characteristics

The scoring for included studies is presented in Table 2 (other characteristics continued in Tables S2 and S3 as supplementary material). Katsnelson¹⁹ included four studies²⁰⁻²³ searched between 1966 and May 2010. Al-Moraissi et al.²⁴ included 16 publications^{20-23,25-36} (nine retrospective studies and seven controlled clinical trials) searched in December 2013 without date restrictions. Ma et al.³⁷ included eight retrospective cohort studies

Table 2: Main characteristics and quality assessment scores obtained using AMSTAR and Glenny et al. checklist

Authors	Reference number	No. of studies included	Outcome measures	AMSTAR score (lowest 0, highest 11)	Checklist of Glenny et al. (lowest 0, highest 14)
Katsnelson	19	4	Maximal inter-incisal opening	8	7
Al-Moraissi	24	16	Maximal inter-incisal opening	11	10
Ma et al.	37	8	Maximal inter-incisal opening and incidence of reankylosis	11	12
Ma et al.	38	8	Maximal inter-incisal opening and incidence of reankylosis	11	13
De Roo et al.	41	38	Maximal inter-incisal opening	11	11
Mittal et al.	5	26	Incidence of reankylosis and maximal inter-incisal opening	11	11

Table 3: AMSTAR checklist and the number of studies that satisfied each of the criteria

S. no.	AMSTAR questions	Katsnelson ¹⁹	Al-Moraissi et al. ²⁴	Ma et al. ³⁷	Ma et al. ³⁸	De Roo et al. ⁴¹	Mittal et al. ⁵
1	Was an <i>a priori</i> design provided?	Yes	Yes	Yes	Yes	Yes	Yes
2	Is there a duplicate study selection and data extraction?	Yes	Yes	Yes	Yes	Yes	Yes
3	Was a comprehensive literature search performed?	Yes	Yes	Yes	Yes	Yes	Yes
4	Was the status of the publication (i.e., grey literature) used as an inclusion criterion?	Yes, no mention of grey literature	Yes, no mention of grey literature	Yes, no mention of grey literature	Yes, no mention of grey literature	Yes, no mention of grey literature	Yes, no mention of grey literature
5	Was a list of studies (included and excluded) provided?	No	Yes	Yes	Yes, but no list of excluded studies	Yes, but no record of excluded studies	Yes
6	Were the characteristics of the included studies provided?	Yes	Yes	Yes	Yes	Yes	Yes
7	Was the scientific quality of the included studies assessed and documented?	No	Yes	Yes	Yes	Yes	Yes
8	Was the scientific quality of the included studies used appropriately in formulating conclusions?	Yes	Yes	Yes	Yes	Yes, using a customized framework	Yes
9	Were the methods used to combine the findings of studies appropriate?	Yes	Yes	Yes	Yes	Yes	Yes
10	Was the likelihood of publication bias assessed?	Yes	Yes	Yes	Yes	Yes	Yes
11	Was the conflict of interest stated?	No	Yes	Yes	Yes	Yes	Yes

and were searched up to October 11, 2014. Ma et al.³⁸ published one more study that included eight studies^{23,26,28,30,31,36,39,40} searched between 1946 and July 28, 2014. De Roo et al.⁴¹ publication included 38 studies^{21-23,28,31,42-73} with four prospective and one RCT, and other study types were not mentioned. Mittal et al.⁵ included 26 studies^{20-23,26-28,30-32,34,39,40,48,53,66,72,74-82} for MA.

Quality Assessment

None of the published reviews included in this overview met all the AMSTAR criteria (Table 3). The scores ranged from 8 points to

11 points. Point 4 of the AMSTAR guideline was partly explained in all publications. One study¹⁹ received the lowest score indicating poorly performed study involving four articles for review and MA, whereas the other publications^{5,24,37,38,41} received a score of 11. Two of the MA were published in the same year by the same author with different objectives involving eight studies each for MA.^{37,38}

The scores for the Glenny et al.¹⁰ checklist varied between 7 points and 13 points (Table 4). Spearman’s correlation was positive between the scores of two quality assessment tools, with a coefficient of 0.66 ($p = 0.15$) (Fig. 1). The mean and SD score for

Table 4: Checklist of Glenny et al. and the number of studies that satisfied each of the criteria

5	Were all languages considered?	Not mentioned	Yes	Not mentioned	Yes	Yes	Not mentioned
6	Was any hand-searching carried out?	Yes	Yes	Yes	Yes	Yes	Yes
7	Was it stated that at least two reviewers applied the inclusion criteria?	No, one author performed	Not mentioned	Yes	Yes	Yes	Yes
8	Did reviewers attempt to assess the quality of the included studies?	Partly assessed using publication bias	Assessed	Yes	Yes	Yes	Yes
9	If so, did they include this quality assessment in the analysis?	No, only publication bias assessed	Yes	Yes	Yes	No	Yes
10	Was it stated that the quality assessment was carried out by at least two reviewers?	No	No	Yes	Yes	No	Not mentioned
11	If the results have been combined, was it reasonable to do so?	Yes	Yes	Yes	Yes	Yes	Yes
12	Are the results clearly displayed?	Yes	Yes	Yes	Yes	Yes	Yes
13	Was an assessment of heterogeneity made, and were reasons for variation discussed?	No	Yes	Yes	Yes	Yes	Yes
14	Were the results of the review interpreted appropriately?	Yes	Yes	Yes	Yes	Yes	Yes

AMSTAR was 10.50 ± 1.22 and for Glenny et al. was 10.67 ± 2.06 (Table S4 supplementary material).

DISCUSSION

This overview is limited to SRs with a MA that evaluated the various surgical techniques used in the management of TMJA and its outcomes in humans. The TMJA prognosis is multifactorial; to date, no consensus on the standards of care has been advised. It might be attributed to patient and clinician factors broadly. Many attempts have been made in the past to assess the published literature.^{5,19,24,37,38,41} Few SRs are published with and without MA.^{5,14,15,19,24,37,38,41} Surprisingly, it was noted that variations in the number of included studies despite almost the same outcomes are being evaluated and published in the same year and same journal.^{37,41} This variation might be attributed to the inclusion and

exclusion criteria. Despite the increased number of publications, the quality of the publications has not reached the highest scoring.

The recent study⁵ is published after a gap of 4 years from the last published literature,⁴¹ but it includes a lesser number of studies compared to the previous research for interpretation even though the scope has been broadened by adding the distraction osteogenesis.⁵ The lack of inclusiveness of the previous MA (Ma et al., 2015^{37,38}) in discussion indicates methodological flaws in the search criteria.⁴¹ So, a more rigorous researching and reviewing approach is necessary for better evidence and conclusive remarks. The authors have not found the Prospero/Cochrane protocol for the published studies included in this overview. The SRs with or without MA should register its protocol in Prospero or Cochrane systemic protocol reviews for validity, which in turn prevents duplication of studies and methodological flaws. Leaving apart the Kabans protocol, the existing literature is unable to draw any further

Fig. 1: Correlation between AMSTAR and Glennly et al. scores

conclusive remarks.^{6,7} So, the readers should exercise caution while adopting the interpretation and conclusive remarks.

The increase in scoring indicates an improvement in the reporting pattern from the first MA¹⁹ (the year 2012) to the latest published⁵ (the year 2019). The number of published articles were increased because of the shift of the thought process from gap arthroplasty to interposition arthroplasty and reconstruction arthroplasty using various techniques that have widened the scope of the study.^{5,19,24,37,38,41} This paradigm shift in surgical management made the prognosis better with reduced postoperative complications and improved patient compliance, function, and aesthetics. The reporting quality of RCT, controlled clinical trial (CCT), or case series needs to be improved for better evidence.⁸³ None of the published studies reported TMJA classification before intervention, so it might have given a better edge for correlation of the surgical method and prognosis. Although the publications reviewed had similar objectives in this overview, but they had high methodological heterogeneity. However, these SRs did not meet all of the criteria of the checklists used, indicating potential publication bias.

The risk of bias assessment is essential for individual studies.⁸³ Adopting the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach for the synthesis of evidence would be a significant step for improving the quality of clinical evidence.⁸³ The International Committee of Medical Journal Editors (ICMJE)⁸⁴ set many reporting guidelines for human clinical series or CCT or RCT publications. If authors adhere strictly to these reporting criteria, then better evidence can be provided, which can be universally adopted for developing the TMJA treatment protocol. High-quality reviews may help the clinicians and patients to have the best possible results.⁸³ The publication bias assessment and homogeneity are fundamental for the studies considered in MA.^{2,3} These factors clarify the reader the methodological quality opted for the same. Quality assessments, such as the Cochrane Collaboration's tool for assessing the risk of bias for RCTs and Newcastle–Ottawa Quality Assessment Scale for cohort studies, were used in the included studies.

The TMJA surgical management outcome analysis consists of several confounding factors. Some of them should be included in inclusion or exclusion criteria so that the effect can be minimized.

The time duration of ankylosis, type, age, treatment provided, postsurgical monitoring, etc., are important factors along with the surgical expertise of the clinicians for the better outcome. Even though the study included extensive quality checks using checklists but these lists lack of quantitative assessment. In our study, the lowest score obtained was 7. Despite the lack of standard reference scale for discrimination as poor or good study, the score below 3 was considered as poorly designed.^{4,85} But in our overview, we found moderate scored reviews.

The checklists used in this overview are more comprehensive and were used extensively with validation for the quality checks. Many other tools are available but are not so comprehensive and not provide scoring.^{9,11,12,86–88} Because of the scoring, it is possible to correlate using Spearman's correlation, which measures the relationship between two variables. So, we have used these two checklists. In this study, the scores were positively correlated, indicating a lower possibility of errors and a lower risk of bias in the scoring system implemented.

The study has limited the critical assessment to the English language literature archived in the Medline database for the accuracy, reproducibility, and quality of publications for evaluation. The increase in predatory journal publications is worrying some for the evidence published, and the involvement of such studies as reference might mislead the outcome or recommendation.^{13,84}

CONCLUSION

The clinicians and researchers, as a result of this, advised to look after the reporting guidelines and adhere to the protocol of reviews for better evidence. Authors cautioned to refer the valid, researchable, and indexed journals for better validity as few of the MA referenced predatory journals in their research, which may undermine the objective of SR and MA. The word of caution is always better for better evidence creation for the future generation and the standard of care.

AUTHOR CONTRIBUTIONS

Vivekanand S Kattimani and Abhishek Jairaj drafted the protocol; Vivekanand S Kattimani, Abhishek Jairaj, and Shaik Parveen Sultana developed a search strategy. Team 1, Vivekanand S Kattimani, Abhishek Jairaj, Shaik Parveen Sultana, and Team 2, Nikhil O Govindan, Paul Mathai, Swati Sahu, Abhishek Patley, searched for literature. Vivekanand S Kattimani, Abhishek Jairaj, and Swati Sahu selected articles to include in this analysis. Paul Mathai and Abhishek Patley obtained copies of publications of all included studies. Vivekanand S Kattimani, Nikhil O Govindan and Swati Sahu extracted data from publications. Abhishek Jairaj and Shaik Parveen Sultana verified the data entered for analysis. Shaik Parveen Sultana carried out the analysis part. Vivekanand S Kattimani, Abhishek Jairaj, and Shaik Parveen Sultana interpreted the analysis; Vivekanand S Kattimani and Abhishek Jairaj drafted the final review. All the authors read and approved the final version.

ETHICAL APPROVAL

Not required, as it does not involve humans or animals in the study.
